DOCUMENT RESUME

ED 056 238 VT 014 237

TITLE	Microfiche Collection of Clearinghouse Documents Reported in Abstracts of Instructional Materials in Vocational and Technical Education (AIM), Fall 1971.
INSTITUTION	Ohio State Univ., Columbus. Center for Vocational and Technical Education.
SPONS AGENCY	Office of Education (DHEW), Washington, D.C.
PUB DATE	71
NOTE	22,850p.
EDRS PRICE	MF-$71.63 HC Not Available from EDRS.
DESCRIPTORS	Agricultural Education; Business Education; Distributive Education; Documentation; Health Occupations Education; Home Economics Education; Indexes (Locaters); Industrial Arts; Information Retrieval; *Information Storage; *Instructional Materials; *Microfiche; *Technical Education; Trade and Industrial Education; *Vocational Education

ABSTRACT

Documents announced with VT numbers only in the Fall 1971 issue (VT 014 129) of "Abstracts of Instructional Materials in Vocational and Technical Education" (AIM) are included in this microfiche set. The microfiche set is arranged in the following sequence: (1) a Vocational Technical (VT) number index to documents in the microfiche collection, (2) the subject and author index from AIM, and (3) the full text of documents listed in the VT number index. The texts are filmed continuously in VT number sequence. (CD)

INTRODUCTION

This collection of microfiche consists of the documents which are announced with VT number only in the Fall 1971 issue of Abstracts of Instructional Materials in Vocational and Technical Education (AIM). Microfiche availability is shown in the resume as MF AVAILABLE IN VT-ERIC SET. The documents are grouped in VT number sequence and filmed continuously as a microfiche set. These documents are not available on microfiche as individual items, but are obtainable only through purchase of this set, or from agencies who have this set and have the capability of reproducing microfiche. The microfiche set includes the following sections:

1. Vocational Technical (VT) Number Index to Microfiche Collection of Clearinghouse Documents Reported in AIM, Fall 1971.

2. Selected indexes from AIM, Fall 1971.

   a. Subject Index
   b. Personal and Institutional Author Index

   The documents identified in the indexes with an ERIC Document (ED) number are usually available as separate documents from the ERIC Document Reproduction Service (EDRS). Information about EDRS Service can be found in AIM or Research in Education (RIE).[1] Items not available through EDRS will include a source of availability. The page numbers shown in these indexes refer to the location of the abstracts in AIM, Fall 1971.

3. The full text of documents listed in the Vocational Technical (VT) Number Index to Microfiche Collection of Clearinghouse Documents Reported in AIM, Fall 1971.

[1] Research in Education is published 12 times a year. The first issue was no. 1, November 1966. Subscription: Domestic $21.00 a year; foreign $5.25 additional. Single copy: Domestic, $1.75. Send check or money order (no stamps) to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402

VT 012 680 23
Course Outline for Introduction to the World of Work (Seventh Grade).

SUBJECT AND IDENTIFIER INDEX

PAGE

VT 013 068 43
Industrial Physics, Five-Year Program Grades 11 and 12.
VT 013 310 52
Radar Speed Detection.

COURSE DESCRIPTIONS
VT 011 363 7
Industrial Arts Curriculum Guide for the State of Wyoming Grades K-12.

CURRICULUM DEVELOPMENT
VT 011 898 9
Leadership in Curriculum Development; A Handbook for Teachers, School Administrators, and Consultants.
VT 012 701 25
The Use of Behavioral Objectives in the Pre-Employment Laboratory Curriculum of Distributive Education.
VT 012 899 38
Industrial Arts Power Mechanics.
VT 013 335 54
Highway Safety Program Management, A Syllabus.

CURRICULUM GUIDES
VT 002 004 2
An Experimental Resource Unit in Plastics for Industrial Arts.
VT 003 408 2
Curriculum Guide for Family Relations, Grade Twelve.
VT 005 291 3
Plastics Education Guide.
VT 008 496 4
Radio and Television. Curriculum Guides in Trade and Industrial Education.
VT 011 363 7
Industrial Arts Curriculum Guide for the State of Wyoming Grades K-12.
VT 011 898 9
Leadership in Curriculum Development; A Handbook for Teachers, School Administrators, and Consultants.
VT 011 919 10
Suggested Curriculum in Office Occupations.
VT 011 920 10
Auto Damage Correction Occupations.
VT 011 938 10
Shorthand for High Schools.
VT 012 266 14
Training Program for Housing Maintenance Employees.
VT 012 271 14
Guidelines for Family Life and Sex Education, Grades K-12.
VT 012 370 15
Mechanical and Electrical Technology. Resource Guide for Effective Instruction in Industrial Arts.

PAGE

VT 012 371 16
Materials Technology. Resource Guide for Effective Instruction in Industrial Arts.
VT 012 372 16
Visual Communication Technology. Resource Guide for Effective Instruction in Industrial Arts.
VT 012 392 17
An Instructor's Guide for a Program in Tuneup Services.
VT 012 510 17
Moving Products into Agricultural Firms. Seven Teaching Source Units for Agricultural Occupations Other than Farming.
VT 012 511 18
Handling Products and Personnel in Agricultural Firms. Teaching Source Units for Agricultural Occupations Other than Farming.
VT 012 627 20
Numerical Control of Machine Tools, Point-to-Point System. A Suggested Guide for a Training Course.
VT 012 632 21
Curriculum Guide for Trades and Industries Building Construction Programs.
VT 012 660 22
A Curriculum Guide for Aerospace Education (K-12).
VT 012 682 23
Course Outline for Vocational Orientation (Ninth Grade).
VT 012 683 24
Electricity--Electronics. Syllabus in Technical Subjects, (Tentative).
VT 012 684 24
Mechanical Technology. Syllabus in Technical Subjects.
VT 012 706 26
Housing Management Training Program. Community Development Training.
VT 012 734 27
Airframe Maintenance Technician Curriculum. An Experimental Program.
VT 012 751 28
Machine Shop.
VT 012 753 28
Power and Transportation 1-6 and Automotive Engine Tune-Up 1-2.
VT 012 760 29
Powerplant Maintenance Technician Curriculum. An Experimental Program for Vocational and Technical High Schools.
VT 013 005 41
Dairy. Unit (Module): Managing the Dairy Herd.
VT 013 006 41
Dairy. Unit (Module): Getting Started in Dairying.
VT 013 069 43
Mechanical Trade Drafting Syllabus.

SUBJECT AND IDENTIFIER INDEX

Defensive Driving Course. Instructors Manual.
VT 013 445 57
A Guide for Operating Ambulance Fleets.

ECONOMIC OPPORTUNITIES
VT 012 539 ED 048 469 18
A Teacher's Guide on Cooperative Enterprise in the American Economy.

EDUCABLE MENTALLY HANDICAPPED
VT 012 915 ED (SEE AUG '71 RIE) 39
VIEW of the Handicapped (Pilot Program). Teachers Guide and Index.

EDUCATION PROFESSIONS DEVELOPMENT ACT
VT 011 748 8
Functions of Industry.

EDUCATIONAL PROGRAMS
VT 011 868 8
Quantity Food Preparation; A Suggested Guide.

ELECTRIC CIRCUITS
VT 013 124 44
Auto Mechanics Course. Book 2: Simple DC Circuits.

ELECTRICAL APPLIANCE SERVICEMEN
VT 012 554 18
Maintaining the Lighting and Wiring System.

ELECTRICAL SYSTEMS
VT 012 377 16
An Instructor's Guide for a Program in Electrical Services. Automotive Industries Occupations.
VT 013 126 45
Auto Mechanics Course. Book 4: Automotive Electrical Systems, Part I.
VT 013 127 45
Auto Mechanics Course. Book 5: Automotive Electrical System, PartII.
VT 013 128 45
Auto Mechanics Course. Book 6: Automotive Electrical Systems, Part III.

ELECTRICIANS
VT 012 771 30
Electrician's Mate 3 and 2. Navy Training Course.

ELECTRICITY
VT 012 351 15
Understanding Electricity and Electrical Terms, Their Meaning and Use.
VT 012 370 15
Mechanical and Electrical Technology. Resource Guide for Effective Instruction in Industrial Arts.
VT 012 683 24
Electricity--Electronics. Syllabus in Technical Subjects, (Tentative).
VT 012 771 30
Electrician's Mate 3 and 2. Navy Training Course.
VT 012 900 38
Electronics Laboratory Manual--I.
VT 012 901 38
Electronics Laboratory Manual--II.
VT 012 902 39
Introduction to Electronics for Electrical and Electronics Students, Part I.
VT 012 903 39
Introduction to Electronics for Electrical and Electronics Students, Part 2.

ELECTRONIC EQUIPMENT
VT 013 275 49
Smith and Wesson TDS Computer (Time--Distance--Speed). Operating Instructions and Trial Guide.

ELECTRONIC TECHNICIANS
VT 008 298 4
Aviation Electronics Technician 1 and C.
VT 012 683 24
Electricity--Electronics. Syllabus in Technical Subjects, (Tentative).
VT 012 703 26
Electronics Technician 3 and 2. Navy Training Course.
VT 012 787 33
Transistors and Printed Circuits. Instructor's Guide for Maintenance Technician Training.
VT 012 789 33
Aviation Electronics Technician 3 and 2. Rate Training Manual.

ELECTRONICS
VT 008 496 4
Radio and Television. Curriculum Guides in Trade and Industrial Education.

COOPERATIVE INDUSTRIAL AND DISTRIBUTIVE EDUCATION

The Director of Cooperative Industrial and Distributive Education is responsible for part-time Cooperative Industrial Education programs. Preparatory and Cooperative Distributive Education programs, and combinations of these which are called Cooperative Occupational Education. These programs may be organized in high schools, area schools and junior or community colleges.

Cooperative Industrial Education

Instruction combined with part-time employment shall be designed to develop vocational competency for gainful employment in a trade or industrial occupation. These occupations are identified in the Dictionary of Occupational Titles as generally including, but not limited to, the classifications of skilled trades, or semi-skilled occupations which directly contribute to the designing, producing, processing, fabricating, assembling, testing, modifying, maintaining, servicing, or repairing of any product or commodity. Other occupations of technical or service nature usually regarded as trade and industrial may be included.

Instruction may be provided for persons over 14 years of age who have entered or agreed to enter a trade or industrial occupation. For those who have entered employment the instruction must be limited to vocational and technical subject matter related to the occupation or occupational field of employment. For those enrollees who have been identified as socio-economic or academically handicapped, basic general instruction can be provided to reduce the handicaps and to enable them to benefit from vocational instruction planned for them in a vocational program. This group can be served as potential enrollees of a Cooperative Industrial Education program.

Cooperative classes for industrial trainees may be offered to persons enrolled in high school by cooperative arrangements between the school and employers to combine supervised practical experience which is part-time employment with classroom instruction that is vocational, supplemental and related to employment. The arrangements between the school and employers shall be in writing. The employment of the student-learner shall conform with Federal, State and local laws and shall not result in exploitation of the student-learner for private gain. Schools granting a unit of high school credit for supervised occupational experience shall require a minimum of 15 hours per week for the school year. Suggested basic plans for related classroom instruction in part-time Cooperative classes for industrial trainees are as follows:

Plan A. Two years of one class period per day for vocational instruction that is limited to trade and industrial trainees.

Plan B. One year of two class periods per day for vocational instruction that is limited to trade and industrial trainees.

Plan C. One year of one class period per day for vocational instruction that is limited to trade and industrial trainees who have had or are currently enrolled in a course that makes a significant contribution to occupational competency such as those in home economics, agriculture, industrial, and technical education or a specific employment oriented course designed as pre-employment vocational instruction.

Plan D. A deviation from Plan A, B, and C such as:

a. In schools having too few twelfth grade applicants for economy of instruction, eleventh grade trainees may also be enrolled, but an adequate number of second year enrollees should be attracted to schedule them in a separate class period from first year student-learners.

b. In schools desiring to serve the socio-economic handicapped, the grade level, ages, and instruction time shall be based upon the needs of the group served.

Certification and/or approval of cooperative industrial education teacher-coordinators shall be based upon the qualifications for vocational instructional personnel written in the state plan as follows:

a. Occupational experience -- Three or more years of employment or other experience that contributes directly to the competency required in the occupations or occupational area to be taught. Such experience shall have been of such nature and quality as to give a recognized status in the occupation represented. Graduation from a four-year college with a major in the vocational area to be taught or completion of a two-year preparatory vocational or technical program in the occupational area to be taught may be considered as meeting one year of the above experience requirement.

b. Professional training for teaching -- A minimum of 20 semester hours of professional training for teaching, eight of which must be approved vocational teacher preparation. The foregoing must be appropriate to the level of instruction and to the occupation or occupational area to be taught.

c. Technical subject matter -- Individuals approved to teach vocational classes and/or coordinate vocational programs in these areas will be required to have a baccalaureate degree with a major appropriate to the vocational area to be taught.

More specifically stated the qualifications for cooperative industrial education teacher-coordinators are as follows:

a. A baccalaureate degree.

b. Twenty semester hours of professional education with eight semester hours of approved professional preparation in vocational education courses.

c. Twenty semester hours of approved subject-matter courses contributing to a background of knowledge for classroom instruction and employment supervision including appropriate courses in guidance, psychology, sociology, economics, business or industrial education.

d. Two years of approved occupational experience that is appropriate to the occupational field or area of responsibility for coordination and/or teaching assignment.

Cooperative and Preparatory Distributive Education

Instruction shall be designed to develop competency for gainful employment in distributive occupations. Distributive occupations are those followed by proprietors, managers, or employees engaged primarily in the marketing of goods and services. These occupations are commonly in business establishments engaged in retailing, wholesaling, manufacturing, storing, transporting, financing, and risk bearing. The program of instruction shall be derived from the functions of marketing and a knowledge of products and services. The functions of marketing are buying, selling, sales promotion, market research, operations and management. The instruction may also develop social competency and basic skills in communications and calculations associated with the competencies required for employment in distributive occupations.

This instruction may be provided for persons over 14 years of age who are preparing to enter or have entered a distributive occupation. A part-time program in distributive education shall require cooperative arrangements in writing between the school providing vocational instruction to student-learners in the classes and the employers providing on-the-job training through part-time employment of such student-learners. Such arrangements shall provide for employment in conformity with Federal, State and local laws and in a manner not resulting in exploitation of such student-learner for private gain and an organized plan for on-the-job training and supplemental vocational instruction in school. If school credit is granted, fifteen hours per week for a school year shall equal a unit of high school credit.

High school programs may be organized as a cooperative plan providing classroom instruction and supervised practical experience which is regular part-time employment. Programs may also be organized as a project plan for preparatory classes using participation activities supplemental to classroom instruction other than regular part-time employment. The project plan may consist of such courses as Merchandising, Salesmanship, Management and Marketing. A cooperative plan and a project plan may both be organized in the same school. A cooperative plan for part-time students employed in distributive occupations may be organized for classroom instruction as follows:

Plan A. Two years of at least one class period per day for vocational instruction that is limited to distributive trainees.

Plan B. One year of at least two class periods per day for vocational instruction that is limited to distributive trainees.

Plan C. One year of at least one class period per day for vocational instruction limited to distributive trainees: (a) who have completed one unit (two semesters) of preparatory distributive education subjects or (b) who are currently enrolled in an additional distributive subject or (c) who have completed at least two units (four semesters) of instruction in another program approved in the State Plan.

Plan D. A deviation from Plan A, B, and C such as:

a. A class organized specifically to serve academic socio-economic handicapped or potential dropouts may enroll youth over 14 years of age and adapt a work-study schedule to meet their needs.

b. A summer program with classroom instruction and employment hours approximately equal to a semester of Plan A may be organized if taught and coordinated by a qualified teacher-coordinator.

Project plans for preparatory classes utilizing participation activities as supplementary learning experiences, other than regular part-time employment, are as follows:

Plan E. Two school years of at least one period per day for vocational classroom instruction in distributive courses. Schools shall be approved for this plan only if currently providing a Plan A, B, C, or D cooperative plan. A series of semester courses with titles such as Marketing, Merchandising, Salesmanship and Management should begin in the 11th grade so that those completing the first year may enroll in a cooperative program and/or a second year of distributive courses during the 12th grade. Every student enrolled becomes a vocational trainee and should graduate with two or more units of credit to be adequately trained for the labor market.

Plan F. One school year of at least two periods per day for vocational classroom instruction in distributive courses. The two or more periods should be for juniors who will enroll in a cooperative program in the senior year or for seniors who will be seeking employment in a distributive occupation after graduation. The content shall develop competencies needed in distributive employment as indicated in the first paragraph of this section on Cooperative and Preparatory Distributive Education.

Certification and/or approval of distributive education teachers or coordinators shall be based upon the qualifications for all vocational instructors and specifically are as follows:

1. A baccalaureate degree

2. Twenty semester hours of professional education with eight semester hours of approved professional preparation in vocational education courses.

3. Fifteen semester hours of approved subject-matter courses that contribute to technical teaching competency from the area of Marketing and other appropriate business education courses.

4. Two years of approved occupational experience that is appropriate to the occupational field or area of responsibility for coordination and/or teaching assignment.

Plan G. One school year of at least one class period per day for vocational instruction enrolling only those who have a specific vocational objective for employment in an occupation requiring very limited skills and knowledge.

Evaluation of preparatory classes in Distributive Education shall be based upon the following criteria:

1. The number continuing training in the part-time cooperative program.

2. The number continuing training in the second year of preparatory instruction.

3. The number entering distributive occupations after graduation from high school.

4. The number enrolling in post-high school instruction which is related to the high school program.

Post Secondary preparatory classes for full-time students in area vocational schools and junior or community colleges may be organized for instruction that develops or improves the competencies for distribution occupations. A program of distributive education shall be not less than two courses per year for two years. Enrollment shall be limited to those with an occupational objective in distribution. Supervised practical experience as regular part-time employment shall be provided only to students enrolled in one or more distributive subjects.

Instructors in post-secondary programs for full-time students shall meet the requirements for certification and/or approval according to the qualifications for all vocational instructional personnel.

Special classes may be provided to meet the needs of academic socio-economic handicapped persons to secure gainful employment in distributive occupations. The program of instuuction may include cooperative arrangements with other vocational areas. The enrollees in a program designed to prepare for specific employment in a distributive occupation may also be provided general instruction that is necessary to enable the student to benefit from vocational instruction in the competencies required by the occupation.

Approval of teachers for special programs shall be by the State Department of Education and based upon qualifications appropriate for the specialized educational responsibility.

Physical facilities shall be provided that are adequate in size to allow space for instructional equipment that resembles a retail store. Instructional equipment should include a cash register, display cases, wrapping facilities, etc. Funds must be available for the purchase of up-to-date instructional materials to teach by the project method and provide participation activities that emphasize the vocational approach to learning. In other words, this must be more than a textbook course. The instruction must comply with current practices in distribution and develop decision making skills that contribute to competency in a distributive occupation. The preparatory courses demand equipment, references, and study guides appropriate for individual interests and abilities. These must be adequate to produce employable people and those entering the cooperative programs must continue to secure specific vocational instruction in the classroom. This calls for much individual study from guides and references designed for developing specific employment responsibilities.

Youth organizations shall be encouraged in local schools as chapters of the Distributive Education Club of America. A state advisor shall be provided and financial assistance shall be offered whenever it is legal or established state policy. Local clubs shall be expected to have an active local program and participate in the state-wide activities designed to provide desirable educational experiences for youth.

Cooperative Occupational Education

Cooperative Occupational Education designates a part-time cooperative training program that is a combination of Cooperative Industrial, Cooperative Distributive and in some instances Cooperative Office Education. The name of this program emphasizes the method of learning without identifying the subject matter, discipline, or occupational fields of training. The common significant feature is the use of supervised occupational experience to supplement vocational classroom instruction or the provision for in-school vocational instruction related to part-time employment.

Classes, enrollees and part-time employment must meet the general requirements for all vocational education under the 1963 Act, and the specific requirements for Cooperative Industrial Education and Cooperative Distributive Education. When supervised occupational experience in office occupations is included, the requirements for Business and Office Education shall be met.

This part-time cooperative program requires local schools to have cooperative arrangements in writing between the school providing vocational instruction to student-learners in the classes and the employers providing on-the-job training through part-time employment of the student-learners. Such arrangements shall provide for employment in conformity with Federal, State and local laws and in a manner not resulting in exploitation of the student-learners and shall provide for an organized plan of on-the-job experiences coordinated with supplemental vocational instruction in school. Regular part-time employment of fifteen hours per week for a school year shall be required for a unit of high school credit. The plans for classroom instruction of part-time cooperative enrollees are as follows:

Plan A. Two years of at least one class period per day for vocational instruction that is taught by a coordinator to separate class sections for distributive and industrial trainees.

Plan B. One year of at least two class periods per day for vocational instruction that is taught by a coordinator to separate class sections for distributive and industrial trainees.

Plan C. One year of at least one class period per day for vocational instruction that is taught by a coordinator to separate class sections of distributive and industrial trainees providing the distributive trainees have completed one full-year course of preparatory distributive education or are currently enrolled in a distributive subject and providing the industrial trainees have completed one full year or are currently enrolled in a course that makes a significant contribution toward occupational competency.

Plan D. A deviation from Plan A, B and C such as:

(a) In communities of less than 5,000 distributive and indusrtial trainees may be combined in the same class.

(b) In schools with too few trainees to have more than one class section distributive and industrial trainees may be combined in the same class.

(c) In schools with schedule conditions that can be justified as unsuited to separation of distributive and industrial trainees, they may be combined in the same class.

(d) For students classified as having acadmmic socio-economic handicaps, pre-requisite courses and classification of trainees by occupational experience may be disregarded and the length of instruction in years or periods may be provided to suit the needs of the students.

Certification of Cooperative Occupational Education (COE) teacher-coordinators is based upon some common qualifications required for the occupational fields that are combined. They must have a baccalaureate degree, and two years of occupational experience, but there should be a minimum of one year in each occupational field involved. The twenty hours of professional education courses, including semester hours of specific professional preparation in vocational education, is the same for each field. It is only in the technical subject matter background courses that there is a distinct difference. More specifically the combination or Cooperative Occupational Education (COE) teacher-coordinator certification requirements are:

(1) A baccalaureate degree

(2) Twenty semester hours of professional education with eight semester hours of approved professional preparation in vocational education courses.

(3) Twenty semester hours of approved courses contributing to a background of knowledge for classroom instruction and employment supervision. This shall include a minimum of six semester hours in Marketing, Retailing, Merchandising or Salesmanship for any responsibility of teaching student-learners classified as distributive trainees, and a minimum of six semester hours in industrial education for any responsibility of teaching student-learners classified as industrial trainees. The balance shall include appropriate courses in guidance, psychology, sociology, economics or business education.

(4) Two years of approved occupational experience that is appropriate to the occupational field or area of responsibility for coordination and/or teaching assignment.

Youth organizations identified as the Cooperative Occupational Education Club of Missouri shall be encouraged by providing a state advisor and financial assistance as established by state policy.

Procedure for Reporting and Evaluation

Evidence of local operations must be provided to the State Department of Education through periodic reports. In general, details can be given on printed forms that are provided. Details revealed by these reports shall include names of pupils enrolled, their ages, daily schedules, occupational objectives, and places of employment for cooperative and/or supplementary enrollees. The report shall give instruction personnel's daily schedule, total length of employment, contracted salary and certification status.

Local schools shall be expected to keep adequate records of students to make effective follow-up studies for evaluation of the vocational instruction. Specific evaluation reports shall be required and additional evaluations shall be based upon observations of state staff members during periodic visits of local programs.

Reimbursable programs must show evidence of value by the extent of placement and success of enrollees in gainful employment in the occupational field for which they were trained. Financial assistance shall be discontinued for programs failing to show satisfactory evidence of fulfilling this objective of vocational instruction.

The basic reports will be as follows:

1. A contract and budget of expenditures for a fiscal year due by July 30.

2. A semester enrollment report due the third week of each semester.

3. A summary or progress report of the program at the close of the school year.

4. Application for reimbursement on expenditures of salary for time devoted to vocational activities and purchases having prior approval.

5. A follow-up report on vocational students graduating in the spring and due November 1.

6. A follow-up report on vocational students five years after their graduation and due August 15.

ABSTRACT - Developed by the Bureau of Secondary Curriculum Development for the New York State Education Department, this resource unit is for use in modifying industrial arts instruction in the secondary grades to provide for plastic instruction. These materials were developed with two purposes in mind: (1) To provide a guide for content and development of locally designed courses of study, and (2) To provide the most enriched and complete outside resource materials which could be identified. The contents have been arranged in 12 major units: (1) Orientation, (2) Molding and Forming, (3) Moldmaking, (4) Bonding, (5) Laminates, (6) Encapsulation, (7) Forms, (8) Coating, (9) Vinyl Dispersion-Thermofusion, (10) Decorating, (11) Materials, and (12) Guidance. Supply lists and sources of supplies are contained in the appendix. The bibliography is divided into three sections: (1) Basic Library References, (2) Supplemental Reference List, and (3) Free or Inexpensive References. (GEB)

FOREWORD

Today, our lives are increasingly affected by the acceleration of technical knowledge and technological skills.

The increasing complexity of this aerospace age demands that our schools assist youth and adults to keep abreast of current developments. Industrial arts education, within the context of general education, provides a unique practical arts approach. It capitalizes on a student's interest in making things. Industrial arts instruction introduces him to, and acquaints him with, many phases of his environment. These are presented best through direct experiences with tools, materials, and processes. In this way, industrial arts education provides a unique opportunity for young people to gain a general insight into modern industry and to relate their experiences to other educational disciplines.

This *Experimental Resource Unit in Plastics for Industrial Arts Education* is for use in the junior and senior high schools. As an integral part of industrial arts education, it provides unique and significant learning experiences within the context of a total educational program.

Gordon E. Van Hooft
Chief, Bureau of Secondary Curriculum Development

INTRODUCTION

This *Experimental Resource Unit in Plastics for Industrial Arts Education* was developed to fill an emerging need to interpret plastics as a contemporary industrial material, involving different processes and products. Enrichment and modernization of industrial arts education programs in the junior and senior high schools is made possible as current courses of study are modified to include the addition of meaningful instruction in plastics. This publication contains a suggested outline showing how industrial arts instruction in the junior high school may be modified to provide for plastics instruction.

As the result of a survey of the plastics industry in New York, manufacturers of plastic materials and products indicated an interest and willingness to make their facilities available for field visits of students in industrial arts programs. A guide to such possible field trips is contained in the Appendix.

There also is an equipment list, submitted by the committee preparing this publication, which provides detailed information relating to items, possible supplier, and approximate cost at the time of publication.

The Appendix further contains a detailed bibliography. The listed publications include those materials that should be provided as a *Basic Reference Library*. A *Supplemental Reference* list is contained as references for advanced study. Another important section is the *Free or Inexpensive Reference* list.

A two-fold purpose was kept in mind as this material was being developed:

- To provide a guide for content and development of locally designed courses of study
- To provide as enriched and complete outside resource materials as it was possible to identify

It was planned that instruction in plastics would become an integral part of the total program offered in both the junior and senior high schools. Schools are invited to request additional assistance from the Bureau of Industrial Arts Education when considering the addition of plastics instruction to the industrial arts education program.

C. Thomas Olivo
Director, Division of Occupational Education II

Joseph R. Strobel
Assistant Commissioner for Occupational Education

66

TO THE INSTRUCTOR

The significant role of plastics as a material, and of plastics products, is vital to our industrial society. After considerable deliberation it was decided that resource materials should be prepared in a formal way in order to extend, improve, and emphasize the importance of this material and the accompanying processes and products. The content in this publication has been divided into twelve major units. These units have been arranged in a logical order and include from 1 to 11 lessons per unit. The resultant 50 lessons, including 23 demonstrations and 27 related lessons, comprise information appropriate for instructional purposes in industrial arts. The length of presentations should be determined by the teacher as the lessons have not been divided according to a time schedule. The outline technique which has been used lends itself to subdivision within lessons. Schools preparing for instruction in plastics should select units and lesson topics carefully in order to provide a logical teaching-learning progression.

Materials and product manufacturers in the plastics industry of this State are interested and willing to assist teachers in industrial arts education in several ways. Field trips may be planned to gain firsthand knowledge of this rapidly expanding field. A guide to such possible field trips is contained in the Appendix. Teachers should add to the list other industries within a reasonable radius of the local school system where field trips may be provided.

Helpful cooperation was received from the industry in identifying suitable equipment. At the time of publication the cost of basic equipment for instruction in plastics was identified. The prices which appear in the Appendix, therefore, are those that prevailed in 1965. Selection of appropriate equipment to meet local course needs may be determined easily by referring to this list. The necessary equipment for the introduction of plastics instruction may be added to the wood, ceramics and shop drawing instruction units of the junior high school program. It may be combined with equipment from one or more of the other areas of instruction at the senior high school level. It is anticipated that bench surfaces and certain small tools already available for other instructional areas will be used in the plastics activity.

The Appendix contains a supply list and sources of these supplies. No effort has been made to determine the necessary quantity of supplies, but the recommendation is offered that teachers procure suppliers' catalogues and that conservative requests be made for those items having a short shelf life.

The bibliography has been divided into three sections. The first section, entitled *Basic Reference Library*, consists of the publications to which the lessons have been keyed. When plastics instruction is added to the curriculum, this basic library should be included as essential for reference purposes, both for the teacher and the students.

The second section of the bibliography, the *Supplemental Reference List*, includes publications which have been used as references, usually of an advanced nature, in many of the lesson outlines. The references throughout the course of study which have been marked with an asterisk (*) appear on this list of Supplemental References.

The third section of the bibliography, is *Free or Inexpensive References*. Schools introducing plastics instruction should add some of these titles to their reference libraries. Some of the free and inexpensive materials will be found indispensable to the teacher. Terms used frequently throughout the course of study will be found in the *Glossary of Plastic Terms*, available free from Phillips Chemical Company and listed in the bibliography.

The Film Catalog of the Plastics Industry published by the Society of the Plastics Industry will be of value in the selection of audio-visual materials. The content of this catalog was considered to be comprehensive enough to make it unnecessary to include a list in this publication. The curriculum development group previewed approximately 50 films, most of which have been annotated in this SPI publication. All were found to be of high quality and acceptable for industrial arts study purposes.

As stated earlier, the publication was developed with two purposes in mind:

- To provide a series of resource instructional units from which certain units might be selected for instruction at both the junior and senior high school levels.

- To develop a publication containing necessary resource information for teachers unfamiliar with this material area.

Schools are invited to request additional assistance from the Bureau of Industrial Arts Education and to forward constructive suggestions on how this instructional area and the total instructional program may be improved.

Arthur J. Dudley
Chief, Bureau of
Industrial Arts Education

68

ACKNOWLEDGMENTS

This publication was developed during the 1964 summer session at the State University College at Oswego in a curriculum development workshop coordinated by Robert J. Ullery, Associate in Industrial Arts Education, Bureau of Industrial Arts, State Education Department. The facilities of the college were made available for this purpose through the courtesy of Paul DeVore, Director of the Division of Industrial Arts Education.

Technical advisers to the development team included Gerald Steele, of Minneapolis, Minn., and Maurice Keroack of the instructional staff at State University College, Buffalo. Editorial adviser to the group was James Crawford, department chairman, Monroe-Woodbury Central School, Central Valley. An opportunity was provided for the trial use of the instructional materials through the courtesy of Frank Robinson and William Todd at the State University College at Oswego.

The original lesson content was developed by a selected group of six industrial arts teachers including F. Dean Hansen, Burnt Hills-Ballston Lake Central School; Irwin S. Howard, Gates-Chili Central School; Robert Kindred, Niagara Falls Schools; Frank R. Manhardt, North Babylon Schools; Carl J. Marsden, New Rochelle Schools; and Vito Tisci, Ilion Schools.

The resource materials in this publication were prepared under the direction of Arthur F. Ahr, formerly Chief, Bureau of Industrial Arts Education, State Education Department, Albany. Final editing was performed by Robert J. Ullery of that bureau. Final copy was prepared for publication in the Curriculum Development Center by G. Earl Hay, Associate in Vocational Curriculum, Bureau of Secondary Curriculum Development.

Appreciation is extended to the following firms, which made equipment available for experimental, developmental, and general evaluation purposes: Brodhead/Garrett Co.; Canadian Aviation Electronics Inc.; Kamweld Products Co.; and Simplomatic Manufacturing Co.

The following firms cooperated by making plastics materials available: Cope Plastics; Dow Corning, Engineering Products Division; Eastman Chemical Products, Inc.; General Electric Co., Chemical Materials Dept.; Hooker Chemical Corp.; Industrial Arts Supply Co.; Koppers Co., Inc., Plastics Division; Naugatuck, Chemical Division; Portage Plastics; and U.S. Rubber Co.

ACKNOWLEDGMENTS

Publishers of the following periodicals made their publications available for the review of workshop participants: *Canadian Plastics; Maintenance, Inc.; Modern Plastics; Plastics Design and Processing;* and *Plastics Technology*.

Special credit is due several trade associations, including the Society of Plastics Engineers and the Society of the Plastics Industry, which made association publications available and also offered helpful advice concerning the development of the course of study. Recognition is due Joseph Madden, of the Society of the Plastics Industry, William Rogers, Chairman of the Mechanical Technology Department, Farmingdale, and Anver Suleiman, of International Plastics Industry Consultants, Inc., all members of the SPI Education Committee who gave so freely of their time to review copy prior to publication. Also worthy of special recognition for assistance is the National Referral Center for Science and Technology, Library of Congress, Washington, D. C.

The plastics industry, especially New York State plastics processing firms, were helpful,not only in providing equipment, materials, industrial literature, and advice;but also in making possible the directory of field trips contained in this publication.

The Diemolding Corporation of Canastota, Auburn Plastics, and Shoe Form Corporations of Auburn were hosts to the curriculum development group who visited their plants.

Special credit is due to several publishers who made publications and advanced outlines of books available: American Technical Society; Charles A. Bennett Co., Inc.; ILIFFE Books, Ltd., London, England; McGraw-Hill; McKnight & McKnight; Penton Publishing Co.; Reinhold Publishing Co. and Temple Press, Ltd., London, England.

The following made audio-visual materials available for preview by the curriculum development group: Black Clawson Co.; COBA Products Co.; Comet Industries, Inc.; Di-Arco Corp.; Dow Chemical Co.; Dow-Corning Corp.; Eastman Chemical Products, Inc.; Filon Corp.; B. F. Goodrich Chemical Co.; Foudry Process & Chemical Co.; Koppers Co., Inc.; Mobay Chemical Co.; Molded Fiber Glass Boat Co.; Naugatuck Chemical Co.; Owens-Corning Fiberglas Corp.; Phillips Petroleum Co.; Milton Ross Co.; Society of the Plastics Industry, Inc.; Spencer Chemical Co.; Union Carbide Plastics Co.; and Westinghouse Electric Corp.

Those responsible for the development of the manuscript for this publication are indebted to staff members at the State University College at Oswego for their cooperative efforts. Worthy of special note was the untiring assistance afforded by Helen Haggar, librarian.

72

ACKNOWLEDGMENTS

The success of this activity is due also in part to preliminary discussion with both Peter Lachina, teacher at Manhattan Vocational and Technical School, and William Rogers, Long Island Technical Institute at Farmingdale. Credit is also due Bragg Stockton, Vocational Industrial Arts Coordinator, Dallas Independent School District, Dallas, Texas, for providing his school district publication entitled, "Plastics Seminar."

Acknowledgment is made to the staff of the Bureau of Industrial Arts Education for their counsel and assistance during the planning and production of the manuscript.

6.	SPI	Plastics Engineering Handbook	pp. 8, 22, 39, 45, 19, 23

FOR DISCUSSION:

. Common use of plastics in everyday life
. Interdependence of industries
. Development of processing machinery

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Compare the growth of the plastics industry to that of other industries.
. Investigate present use of different plastic materials.

LESSON OUTLINE:

I. Natural Resins

A. Rubber
B. Shellac

II. First Commercial Plastic Discovery in U. S. A

A. John Wesley Hyatt's discovery in 1868
B. Makeup of cellulose nitrate (celluloid)
C. Uses and molding techniques

III. Phenolic Resin Discovery, 1909

A. Search for synthetic shellac - Dr. Leo Henrik Bakeland
B. Developed molding techinques for phenolic
C. Properties and uses

IV. Up to World War II

A. Cold molded, 1909, Phenolics
B. Casein from cows milk 1919 - Adolph Spitteler
C. Cellulose acetate 1927; first injection molded plastic, 1929
D. Introduction of injection molding in USA, 1934
E. Polystyrene 1938

V. During World War II

A. Great need for substitutes due to material shortage
B. Need for new materials with new characteristics
C. Polyethylene 1942, made radar and television possible (flexible electrical insulator)
D. Polyester 1942, made fiber glass reinforced plastics possible

VI. After World War II

A. Slump in use of plastics following World War II
B. Great rise in use of plastics began about 1950
C. New plastics materials and processes developed

VII. Growth Curve of Plastics Production

A. Rapid growth
B. Increase in last 10 years
C. 1963 use, 9 billion pounds; 1964 use, 10 billion pounds

D. According to a study recently made by Corplan Associates, plastics will be second in importance only to steel as an industrial material, increasing from 8 billion pounds in 1963 to 15 billion in 1970. Per capita consumption will increase from 40 pounds to 68.

VIII. Future of the Plastics Industry

A. Unlimited new materials, applications and processes
B. About 3 percent of total market potential realized in 1964

SUMMARY:

In about one hundred years, the plastics industry has grown from discovery to production of nearly 10 billion pounds per year. Even at this rate, only 3 percent of the estimated potential market has been realized. Without plastics, many of our everyday products and services would be impossible. Such things as radar, TV, telephones, and home comforts such as foam cushion, food packaging, and new clothing materials would not be available.

QUESTIONS:

Q: Name the first commercial plastic resin and its inventor.
Q: Name the first commercial thermosetting plastic and its inventor.
Q: Give the reason for the great rise in the development and use of plastics.
Q: What need prompted John Wesley Hyatt to make his discovery?
Q: Name several significant milestones in the history of the plastics industry.

BRIEF DESCRIPTION OF PROCESS:

Manufacturers in many material areas have found that plastics can be utilized to advantage in their products. New uses for plastic products are being found daily. The properties of plastics often make possible manufacturing procedures and products not possible with any other material.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Samples of products which utilize plastics
- Bleach bottles - blow molded
- Rain apparel - calendered film
- Food containers - vacuum formed
- Auto accessories - injection and compression molded
- Distributor caps - compression molded
- Wire insulation - extruded
- Other samples as available

LESSON OUTLINE:

I. Construction

A. Paneling - laminates
B. Counter tops - high pressure laminates
C. Insulation materials - foams
D. Paints - resins
E. Roofing
F. Vinyl tile - extrusion or calendering

II. Transportation

A. Brake Linings - compression
B. Truck and car bodies - reinforced plastics
C. Boats - reinforced plastics
D. Accessory knobs - injection or compression
E. Tires - vulcanizing

III. Farming

A. Greenhouse covers - calendering
B. Irrigation lines - extrusion
C. Baling twines - filament forming
D. Sheet covers to prevent weed growth - calendering

IV. Packaging

A. Bags - blown film
B. Thin wall containers - vacuum forming
C. Shrink pack - blown film
D. Cushioning - foams
E. Shipping drums - thermofusion
F. Lids or covers - injection molding

V. Aero space

A. Nose cones - filament winding or FRP (Fiberglas reinforced plastics)
B. Insulation - foams
C. Foam in place (shock absorption) - foams
D. Satellites
E. Control panels - extruded wire coating

VI. Electrical

A. Switches - compression
B. Terminal boards - lamination and electroplating
C. Circuit breakers - compression
D. Wire insulation - extrusion
E. Printed circuitry - electroplating

VII. Plumbing

A. Pipes - extrusion
B. Valve seats - injection
C. Pipe fittings - injection

VIII. Clothing

A. Synthetic fabric - filament forming
B. Water repellent clothing - coating
C. Insulated clothing - foams
D. Corfom shoes - foams

IX. Home consumer products

A. Measuring spoons - injection
B. Mixing bowls - injection
C. Dishpans - injection
D. Lamps - reinforced plastics
E. Ash trays - compression
F. Appliances - thermoforming and others
G. Teflon coated pans

X. Advertising

A. Counter displays - thermoforming
B. Metalized signs - metalizing
C. Novelty items - injection
D. Vacuum formed signs - thermoforming

XI. Metal Industries

A. Die facings - reinforcing
B. Bearings - injection
C. Drill bushings - injection
D. Inspection gauges

XII. Graphic Arts

A. Offset printing plates

SUMMARY:

In the United States today there are over 5,700 companies which make plastics their business. These companies may be divided into three main categories, having functions which sometimes overlap. These categories are (1) the plastics materials manufacturers which produce the basic plastic resin or compound, (2) the processors who convert the plastic into a solid shape, and (3) the fabricators and finishers who fashion and decorate the plastic. It is of this third category that other industries will make their demands on production in the plastic industries. The plastic material manufacturers estimate that 10 billion pounds of plastics will be used in 1965.

QUESTIONS:

Q: How important are plastics in the American industrial scene?
Q: What are some of the practical or obvious uses of plastic items?
Q: List some of the typical current uses of plastics.

Lesson 3

Related Lesson: Classification and Identification of Plastics

THERMOSETS

Chemical and Trade Names	Physical Characteristics	Typical Uses
1. EPOXY - Plastic Steel Metalfil, Araldite Epon	Low viscosity fluid to a brittle solid; very good adhesion qualities; weather resistant; high mechanical strength; good electrical properties; heat stable; good storage properties; easily colored	Laminating for nose cones, fuel tanks, auto and aircraft bodies, boat hulls (cast); in transformers, rotors, stators, circuit breakers; used for high-voltage low-current insulation, X-ray components, and battery cases
2. MELAMINE - Formaldehyde (Meline)	Strong; hard to scratch; withstands high heat and moisture; full range of colors; odorless, tasteless, nontoxic; oil resistant	Dinnerware; food service items; mixing bowls; table counter tops; auto ignition parts; hearing aid and shaver housings
3. PHENOLICS - Phenol formaldehyde (Phenolic), Bakelite	Strong; hard to scratch; good heat and electric insulation; high resistance to moisture	Flat iron handles; appliance bases; radio and T.V. cabinets; telephones; pot and utensil handles; light plugs and switches
4. POLYESTER - Mylar, Dacron	Strong; hard to scratch; unaffected by water; good resistance to chemicals and heat	Air-conditioner housings; chairs; light panels; bath tubs; skylights; luggage; boats; sleds; sport car bodies; patio roofing; fabrics
5. POLYURETHANE - Polyurethane Arothane, Cipfoam	Foamed plastic similar to rubber; very resilient, returns quickly to original shape after being wrung dry; light weight; heat resistant; good insulation qualities; easily molded; can be laminated	Used extensively as an insulation for refrigerators; pipes; trailers; trucks; panels for home construction; bridges; shelters; storage tanks; linings in clothing, bedding, cushions; cushioning in auto and furniture seats
6. SILICONE - Silastic RTV	Stable at high temperature and also at low temperature; resistant to weathering and oxidation; excellent electrical properties; water repellent; resistant to most gases, chemicals, and solvents	Water proof waxes and polishes; ball bearings; greases; defoamers; cosmetics; electrical insulators; release agents
7. UREA - Arodure, Resimene, Lauxite, Plaskon	Resists breaking and scratching; unaffected by common chemicals, grease, and oils; odorless, tasteless, nontoxic; good electrical insulator	Buttons; buckles; radio cabinets; clock cases; light reflectors; control knobs

Related Lesson: Classification and Identification of Plastics

THERMOPLASTICS

Chemical and Trade Names	Physical Characteristics	Typical Uses
1. A.B.S. (Acrylonitrile-Butadiene-Styrene) ABSON, Royalite, Cycolac	Extremely hard, also can be made flexible; will withstand abuse and pressure; wide temperature range; resistant to chemicals; good abrasion resistance; good impact and flexual strength; excellent thermal stability and hot strength; formable; easily colored	Pipe; luggage; refrigerator and appliance use; shoes; auto instruments; tote boxes; colored telephones; boats; safety helmets; sporting goods; typewriter and pump parts
2. ACRYLIC - Plexiglass, Lucite Orlon, Acrilan	Transparent; light diffusion; weather resistant; exceptionally formable; machinable; shatter resistant	Glazing; lighting; signs and displays; machine guards; models; lenses; coupling filters; textile fiber
3. POLYAMIDE - Zytel Nylon	Very strong; self lubricating; resilient, non-marring; machinable; unaffected by oil	Gears; bearings; wear strips; guides; rollers; stop pins; valve seats; gaskets; hydraulic lubricating lines; fabrics
4. CELLULOSICS - Cellophane, Cellulose Acetate, Rayon Cellulose Acetate Butyrate Cellulose Acetate Propionate	Strong; rough use; scratch resistant; good electric insulator; full range of colors; tasteless, non-toxic	Toys; lamp shades; tool handles; fish lures; ping-pong balls; eyeglass frames; fabrics
5. FLUOROCARBONS - TFE Teflon, (FEP) Teflon, Kel-F, Halon, Fluoride	Chemical resistance; high thermal stability; good dielectric; non-adhesive; low friction	Gaskets; seals; bearings; electronic components; coatings for fabric and metal; sheets; rods and tubing
6. POLYETHYLENE - Martex, Epon, Microthene	Impervious to water; lighter than water; tough; pliable; chemical resistant; dielectric; high frequency insulator	Moisture barrier, protective cover, gaskets, insulating parts, packaging, chemical pipe, high frequency insulators
7. POLYPROPYLENE - Escon, Pro-fax	Light plastic with low specific gravity; strong; good shock resistance; smooth surface; scratch resistance; resistant to acids, bases, and water; flexible; good tensile strength	Electric coffee pots; kitchen utensils; chairs; packaging fiber cloth; clothes; shoes; blankets; luggage; cameras; film
8. POLYSTYRENE - Orienated Styrene	Conventional; exceptional low temperature properties; transparent; brittle	Low temperature electrical parts; refrigerator linings; insulators; lighting panels
9. VINYL - Saran film, Plastisol, (PVC) Polyvinyl Chloride, Poly Vinyl Alcohol	Wear resistant; easy to form; printable; flexes without cracking	Splash aprons; gaskets; seat covers; chemical-beverage and laboratory piping; floor covering

FOR DISCUSSION:

. The injection molding machine and its uses
. Employment opportunities and educational qualirications for employment in injection molding
. Injection molding thermoplastics in a closed mold

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Investigate an occupation in the plastics industry.
. Use the injection molder to mold an article.
. Explore the history of the injection molder or of one of the materials used.
. Experiment with mold-making using various types of materials for injection molding.

Injection Molding
courtesy of The Society of the Plastics Industry, Inc.

BRIEF DESCRIPTION OF THE PROCESS:

Injection molding is accomplished by forcing or squeezing a semi-fluid or plasticized thermoplastic into a mold cavity where it cools to form an article.

MATERIALS, EQUIPMENT AND TEACHING AIDS:

. Injection mold
. Samples of injection molded articles
  - Model airplane - family mold
  - Plastic bottle caps, polyethylene dish pans
. Pellets used in injection molding
. Chart showing section drawing of injection molder
. Chart showing historical development of plastics Ref No. 5 Page 5

LESSON OUTLINE:

I. Historical Development

A. Stuffing machine - 1872, forerunner of the injection molding machine, J. W. Hyatt
  - Heating cylinder-vertical-steam heat
  - Discharge nozzle
  - Hydraulic plunger
  - Used first as an extruder
  - Material used was cellulose nitrate
  - Mold was closed by hydraulics

B. Injection molding, 1919, adapted from die casting machine - Dr. A. Eichengrun
  - Closing mechanism taken from diecast machine
  - Clamping for various thicknesses of molds
  - Used geared mold closing
  - Spring return on plunger
  - Material used was cellulose acetate

C. Injection Molding, 1935 to present
Parallel development of machines and materials; machines modified to meet needs. Ref #5, Page 5
  - Cellulosics 1869
  - Vinyls 1919
  - Polyethylene 1930
  - Polystyrene 1938
  - Nylons 1938, as Filaments; after World War II as a molding plastic

II. The Injection Molding Machine

A. Basic machines contain
  - Mold clamping device which has
    a. A supporting frame to hold mold in place
    b. A clamping device which moves one platen, the other remaining stationary
      . Hydraulically operated
      . Mechanically operated
      . Hydraulic and mechanical
    c. Part removed by air or knockout pins

- Injection unit which has
  a. A supporting frame or base
  b. A feeding device - hopper which feeds by gravity; auxiliary equipment may be added to facilitate drying of the pellets
  c. An injection head which has either
     . A plunger or ram, to force material forward
     . A screw feed
     . A combination of screwfeed and ram called piggy-back
  d. An electrically heated cylinder
  e. A torpedo, for heat conduction
  f. A nozzle - restriction at end of cylinder to increase velocity
     . Single nozzle
     . Multiple nozzle injecting directly into cavity
     . Nozzle torpedo design sometimes varying with type of material used

B. Mold Considerations
- Mold affects quality of article
- Can cause defects in product
- Can increase or decrease production rate
- Molds can be made by casting of epoxies or machining of metal
- Have sprue, gates, and runners to transmit material
- Ejection of articles by pins, air pressure, or stripper plates
- Vents to allow trapped air to escape
- Multiple molding of pieces
  a. Family mold
  b. Multiple cavity mold
- Guide pins for alignment of mold parts
- Cooling of mold-cores or channels for water

III. Industrial Considerations

A. Economics of injection molding
- Short molding cycle
- Low labor costs
- High overhead cost
  . Equipment, from $295 for a 1/5 ounce capacity, to $280,000 for a 200 ounce capacity machine
  . Molds, several thousand dollars each
- Articles of complex design
  Produced more easily by injection molding than other methods
- Long runs necessary to pay for molds
- Low material cost in relation to sheet stock

B. Pressure
- Cylinder pressure from 10,000 to 20,000 psi (25 percent to 75 percent transferred to mold)
- Clamping pressure; mold must be held together or flashing will occur

C. Temperature
- Cylinder temperature higher than material measured with thermocouples
- The material temperature is determined by cylinder temperature and friction. Overheating can cause defects
- Mold temperature is controlled by water or air-cooling

IV. The Industry

A. Started on a large scale in 1930 because material development warranted it
B. Injection molding now the principle method of molding plastics (approximately 60 percent of the production of plastic resins are used for injection molding) Ref. No. 1
C. The average injection molding factory is worth $525,000. See Ref. No. 1

V. Guidance

A. Two types of injection molding establishments
- Custom molders
- Proprietary molders

B. Thousands of employees
- Press operators
- Granulators
- Set-up men and millwrights
- Plumbers
- Engineers

SUMMARY:

The injection molding process is the method by which many plastic articles may be produced. It can produce articles smaller than a golf tee or larger than a garbage can. It uses a variety of thermoplastics. The molding machine itself consists of a feed system, ram or injection section, heating section, and a clamping system which holds the mold.

QUESTIONS:

Q: What is meant by cycle time in injection molding?
Q: Name two plastics that may be injection molded.
Q: What function does the torpedo perform in the injection molder?
Q: Why is the process of injection molding used to produce many plastic articles?
Q: What are the channels called that carry material from the nozzle to the cavity?

UNIT II MOLDING AND FORMING

Lesson 5

Demonstration: Injection molding thermoplastics

OBJECTIVES:

. To acquaint the student with the injection molder

. To relate the safety factors involved in using the injection molder

. To further the students' knowledge of the injection molding process as used in industry

REFERENCES:

1. SPI	Plastics Engineering Handbook	p. 46
2. Redfarn and Bedford	Experimental Plastics	p. 77

FOR DISCUSSION:

. Dry coloring techniques
. Socio-economics and consumer values of injection molded articles

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Make a simple mold to be used on the injection molder.
. Injection mold an object with this mold.
. Evaluate the product from a design standpoint, surface quality, defects due to mold design.
. Run a cost analysis of the mold, time involved, product, and material.
. Experiment with color mixing and color blending.

BRIEF DESCRIPTION OF PROCESS:

In injection molding, a semi-fluid thermoplastic is injected under pressure into a mold where it cools to form an article.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Injection molding machine
. A mold
. Thermoplastic pellets
  - Polyethylene (easiest to use, good molding qualities)
  - Polypropylene (when a stiffer plastic is required)
  - Polystyrene
  - Nylon
  - Others
. Mold releases (silicon spray or wax)
. Information sheet giving terminology of machine in use, melting temperatures of various materials, and procedure for molding an article
. Chart. "Plastics Properties Chart, Modern Plastics Encyclopedia Issue" (A wall chart supplement to Modern Plastics Encyclopedia)
. Injection molded articles
  - Golf tees
  - Bottle caps

LESSON OUTLINE:

I. Terminology

A. Injection unit
- Hopper - material storage and feeding
- Cylinder - (material heating) pressure and heat applied here
- Ram - applies pressure to material
- Nozzle - reduces size of cylinder to increase velocity of material; feeds material into mold
- Source of feed pressure - lever, hydraulic, or air is used

B. Mold clamp or holding device
- Off center or eccentric - most lab machines
- Hydraulic has great holding power
- Platens - 2 aligned surfaces which hold mold together

C. Temperature - approximately 200 to 600 degrees F
- Electrically heated by heat bands around cylinder
- Thermometer - usually thermocouple type; gives cylinder temperature
- Mold temperature - usually room temperature or cooler

II. Process of Molding

A. Preparing plastics material for injection molding
- Bring temperature of cylinder to approximate melting point of desired plastic. (See "Modern Plastics Encyclopedia" Thermoplastics Chart)
- Load pellets into hopper. Note - store pellets in dry, clean place, and, for safety, keep pellets off the floor.
- Ram some pellets into cylinder
- Let plastic soak (heat through). Safety note - DO NOT TOUCH PLASTIC OR NOZZLE.
  a. Semi-fluid as it leaves nozzle
  b. Purge nozzle once or twice to change color; use temperature of material you wanted to remove
- Keep mold cool until material is injected

B. Making the shot
- Place mold against stationary platen
- Adjust clamping device to hold mold together
- Inject material into mold
  a. Pressure at nozzle is approximately 10,000 to 15,000 psi
  b. Stop pressure when resistance is met on hand-operated machine
  c. Stop pressure when plunger stops on air-operated machine
  d. Maintain pressure to allow material to cool under pressure (approx. 5 sec.)
- Release injection pressure
- Release mold pressure and remove mold. (Use caution. Material and nozzle are HOT.)
- Carefully remove object from mold when it is set. (Wear gloves.)

- Inspect for four defects:
  a. Sinking - Material flows away from mold surface; not enough initial pressure; material too hot; pressure not held
  b. Over packing - too much injection pressure; object loses shape when removed
  c. Short shot - too little pressure; material not fluid enough to fill mold; plugged nozzle
  d. Flashing - too much pressure; too little clamp pressure; too hot; ridge forms along parting line of object

C. Finishing
- Remove sprue and runners (diagonal cutters work well)
- Carefully touch rough surface to a soldering iron to smooth

D. Using different colors and materials
- Some machines have removable cylinders and nozzles
- Other machines must be purged (material removed); feed new material in after old is squeezed out at temperature of previous material
- Sprues, runners, and gates may be granulated or reground for reuse

SUMMARY:

Time, heat, and pressure are the three important variable factors in injection molding. There must be a balance of heat, pressure, and time. Various colors and types of materials can be molded by injection molding.

QUESTIONS:

Q: What are some of the causes for flashing on an injection molded product?
Q: How are color or material changes made on an injection molder?
Q: How does the temperature of the cylinder compare to the temperature of the material to be molded in injection molding?
Q: Which material is easiest to mold by injection molding?
Q: Name the three important variables in commercial injection molding.

UNIT II MOLDING AND FORMING

Lesson 6

Related Lesson: Extrusion

OBJECTIVES:

- To convey an understanding of the industrial method of molding plastic called "extrusion"
- To develop an insight into the industrial and consumer applications of extrusions

REFERENCES:

1. *Bernhardt, Ernest C.	Processing of Thermoplastic Materials	Chap. 5
2. *Eastman Chemical Products Inc.	Extrusion	pp. 1-30
3. Edwards, Lauton	Industrial Arts Plastics	pp. 32-33
4. *Griff, Allen L. (Reinhold Pub. Co.)	Plastics Extrusion Technology	pp. 1-288
5. Simonds and Church	Concise Guide to Plastics 2nd Ed.	pp. 165-170
6. SPI	Plastics: The Story of an Industry	pp. 34

FOR DISCUSSION:

- Types of dies used
- Materials adaptable to extrusion
- Industrial and consumer applications of extrusion
- Auxiliary extrusion equipment

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

- Compare extrusion with injection molding techniques.
- Examine commercial products made by extrusion.
- Build or devise a unit so extrusion may be done on an injection molder.

Extrusion Molding
courtesy of The Society of the Plastics Industry, Inc.

BRIEF DESCRIPTION OF THE PROCESS:

Extrusion molding is a process in which thermoplastic materials are formed into continuous sheeting, tubes, profile shapes, rods, film, filaments, or coatings for wire, cable, and cord. Hot plastic material is continuously forced through a steel die by a revolving screw to form these shapes.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Wall diagram of extrusion process
. Samples of extruded products
. Samples of raw materials used for extrusion

LESSON OUTLINE:

I. Applications

A. Rods (lawn furniture frames)
B. Tubing (fluid lines, electrical plug insulators, hose)
C. Sheeting (for vacuum forming, etc.)
D. Blow molding (parison)
E. Coating (wire, cable, cord)
F. Profile shapes (screw driver handles, jewelry)
G. Film (food coverings, seat cover materials, etc.)
H. Polyethylene (parison, the hollow plastic tube from which containers, toys, etc., are blow molded)

II. Materials used for extrusion

A. Styrenes (lawn, patio furniture frames)
B. Vinyls (trim moldings, wire coverings)
C. Nylons (tubes, rods)

III. Principle of extrusion

A. Outgrowth of injection molding
B. Types of extrusion
- Wet extrusion (plunger method, outdated)
- Dry extrusion (screw compacting method)

IV. Industrial equipment

A. Hopper (used to convey materials to cylinder; auxiliary equipment may be added to facilitate drying of the pellets)

B. Heating chamber
- Circulating oil
- Electric heaters

C. Heated screw (special screw for each type of material)

D. Forming dies
- Rod
- Sheet
- Tube, parison
- Coating wire

E. Conveyor (cooling)
- Speed control
- Air jet

V. Industrial production and future outlook

A. As of 1963, the largest number of processors to be found in the field of injection molding, about 20 percent do extrusion and calendering

B. Greater tonnage of thermoplastics processed by extrusion than all other methods of forming in the early sixties

C. Continuous operation extrusion is one of least expensive methods used per volume of material produced

D. Recent developments
- High speed extruder
- Blow molding process adopted by many large industries, thus creating greater demand for extrusion

SUMMARY:

Extrusion is one of the forming methods in plastics, and it is a rapidly growing branch of the industry. The four basic steps of extrusion are heating, compacting, forcing molten plastic continuously through a die under controlled temperature and pressure, and cooling. Thermoplastics materials such as polyethylene, styrene, vinyl, and nylon are those most commonly used for extrusion.

QUESTIONS:

Q: Compare injection molded products with extruded products, as to uses, cost, etc.
Q: What thermoplastic materials are best adapted to extrusion?
Q: What function does the screw perform in an extruder?
Q: Compare injection molding techniques with extrusion techniques.

UNIT II MOLDING AND FORMING

Lesson 7

Demonstration: Principle of extrusion

OBJECTIVE:

. To demonstrate the principles of continuous extrusion

REFERENCES:

1. *Bernhardt, Ernest C.	Processing of Thermo-Plastic Materials	Chap. 5
2. *Eastman Chemical Products, Inc.	"Extrusion"	pp. 1-30
3. Edwards, Lauton	Industrial Arts Plastics	pp. 32-33
4. *Griff, Allen L.	Plastics Extrusion Technology	pp. 1-288
5. Simonds and Church	Concise Guide to Plastics 2nd. Ed.	pp. 165-170
6. SPI	Plastics - The Story of an Industry	p. 34

FOR DISCUSSION:

. Types of dies used to extrude wire, tubing, and sheeting
. Thermoplastic materials adaptable to the process of extrusion
. Industrial methods (use charts and diagrams if an extruder is not available)

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Cut extruded forms to use in jewelry making area.
. Extrude and shape rods for chair frames, tool handles, molding, etc., if extruder is available.

Wire Coating
courtesy of Modern Plastics Encyclopedia

DESCRIPTION OF PROCESS:

Extrusion is a process whereby a thermoplastic material is forced through dies of specific shapes to form tubes, rods, film, and irregular profile shapes.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

- Extruder
- Cake decorator (in lieu of extruder)
- Tube of Polyseam Seal coating
- Thermoplastic pellets (polyethylene, polystyrene, vinyl)
- Plasticized clay (in lieu of pellets)
- Charts, diagrams
- Assorted dies for extruder
- Uncoated wire

LESSON OUTLINE:

1. Demonstration with commercial or laboratory extruder (if available)

   A. Select die and attach to machine

   B. Charge machine
      - Place dry pellets in hopper
      - Use polyethylene, polystyrene, or vinyl

   C. Heat Cycle
      - Adjust temperature of heating chamber to setting recommended for material

   D. Extrude part
      - Screw action of machine compacts material and forces it out of die
      - Part takes shape of die opening

   E. Cool material
      - Air or water can be used
      - Adjust speed of conveyor to regulate tension and size of product

II. Demonstration with cake decorator or cookie press (if regular extruder is not available)

   A. Prepare material to a flow state suitable to pass through die
      - Plasticized clay; play dough

   B. Attach forming die

   C. Feed into chamber (Compare with loading hopper of extruder)

   D. Apply pressure to plunger; refer to diagram in order to explain action of the screw and effects of heat on the pellets

   E. Extrude a part

   F. Dry product; relate to industrial drying methods; move conveyor device at same speed of extrusion

Be97

III. Wire coating demonstration

A. Remove pouring spout from tube of Polyseam Seal plastic
B. Insert 6 inch length of uncoated wire into tube
C. Pass pouring spout over wire and screw into place
D. Squeeze tube to eject plastic while slowly withdrawing wire
E. Allow plastic coating to dry (approx. 1 hr.); compare with industrial cooling methods
- Conveyor speed
- Air jet

SUMMARY:

The basic principles of extrusion are heating, compacting, forcing molten plastic continuously through a die under controlled temperature and pressure; followed by cooling and conveying extruded material. Wire coating is one of the oldest applications of this process.

QUESTIONS:

Write the letter preceeding each term in the right hand column in the space next to each term in the left hand column which most nearly corresponds to the lettered term.

1. ( ) Hopper	A. Cooling
2. ( ) Take off conveyer	B. Drying
3. ( ) Die	C. Thermoset
4. ( ) Polyethylene	D. Thermoplastic
5. ( ) Heating chamber	E. Forming
6. ( ) Feed screw	F. Compacting
7. ( ) Phenolic	G. Reversal
	H. Plasticize

UNIT II MOLDING AND FORMING

Lesson 8

Related Lesson: Blow molding

OBJECTIVES:

. To explain the industrial process used for blow molding thermoplastic products

. To present the consumer applications of blow molding methods

REFERENCES:

1.	Edwards, Lauton	Industrial Arts Plastics	pp. 31-37
2.	*Jones and Mullen	Blow Molding	
3.	Simonds and Church	Concise Guide to Plastics 2nd Edition	pp. 180-182
4.	SPI	Plastics - The Story of an Industry	p. 33
5.	Swanson, Robert S.	Plastics Technology	
6.	Redfarn and Bedford	Experimental Plastics	p. 87

FOR DISCUSSION:

. Development of glass blowing techniques
. Dies and molds used for extrusion of parison
. Special technology
  - Coating
  - Special finishes
  - Food and Drug Administration regulations

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Compare methods of injection molding and extrusion in production of parison.
. Collect various products and determine what thermoplastic, blow molded products are most commonly used in the home.
. Make a blow mold; blow mold an article.

Schematic Illustration of Blow Molding Principle
courtesy of W. R. Grace & Co.

Basic Extrusion/Blowing Principle

BRIEF DESCRIPTION OF PROCESS:

The blow molding process involves the forming of a hollow tube of thermoplastic material, called a parison; by introducing air under pressure into the tube. The heated parison expands and takes the shape of the mold.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Sample products (bottles, containers, etc.)
. Wall chart illustrating parison suspended in mold

LESSON OUTLINE:

I. History

A. Early Egyptians and Babylonians
- Glass blowing

B. Prior to 1958, cellulose acetate
- An art rather than a science
- All equipment manufactured in Europe

C. 1960's, Technological advances
- Mass production methods (parison produced by extrusion)
- Thermoplastic materials
  a. Polyethylene
     - Accounts for 90% of all plastic blow molded products
     - Impervious to solvents
     - Easily molded; fine detail
  b. Polystyrene
  c. Cellulosics
  d. Polypropylene

II. Applications

A. Industrial (gasoline tank liners, glove compartment, containers, and ducts)

B. Home (bottles, lamp bases, and toys)

III. Blow molding process

A. Applications
- Thermoplastic materials (all types can be used)
- Plasticizing material (temperature must be controlled)
- In extruding parison; wall thickness of parison and ratio of expansion determine final thickness of product

B. Molding procedures
- Preparation of parison
  a. Extrusion; may be extruded directly into mold
  b. Gravity effect; the longer the parison the slower the rate of extrusion
  c. Pinch off occurs when mold closes on parison
  d. Use of stock tubing; (heated in an oven)
- Mold materials
  a. Aluminum
  b. Zinc alloy
  c. Brass
  d. Beryllium-copper
  e. Machined steel
  f. Hydrocal and epoxy for short runs

- Blowing method (air injection)
- Cooling (water zoned method)

IV. Industrial Considerations:

Advances in the blow molding process have resulted from refinement of existing techniques. Consolidation of other fabrication methods such as extrusion has caused the growth of blow molding production to rival the growth of the injection molding process since the late 1940s.

Blow molding is used to produce many products formerly produced by the vacuum forming method. The "no seam" construction, derived from the blow molding process, adds strength to the finished product.

V. Consumer Considerations:

Many articles formerly packaged in glass containers are now packaged in plastic containers. The blow molded containers may be reused for mixing and storing solutions, as buoys, etc. Certain solvents, however, will readily permeate the thermoplastic material, rendering the containers unsuitable for reuse.

SUMMARY:

Bottles, containers, etc. may be blow molded by introducing air into the center of a hot extruded tube or parison, causing it to expand and take the shape of the mold. Polyethylene resin accounts for 90 percent of the volume of material used in this rapidly growing area of the plastics industry.

QUESTIONS:

Q: What method is used to form the parison for blow molding?
Q: How is the thickness of a blow molded product controlled?
Q: Blow molding is a refinement of what ancient art?
Q: List several thermoplastic materials used to produce blow molded toys and containers.
Q: How can you identify a blow molded product?

101 SOI

UNIT II MOLDING AND FORMING

Lesson 9

Demonstration: Blow molding

OBJECTIVES:

. To develop an understanding of the blow molding process

. To demonstrate one method of blow molding

REFERENCES:

1.	Edwards, Lauton	Industrial Arts Plastics	pp. 31, 37
2.	Simonds and Church	Concise Guide to Plastics	
3.	SPI	Plastics Engineering Handbook	p. 87
4.	SPI	Plastics: The Story of an Industry	p. 33
5.	Swanson, Robert	Plastics Technology	ch. 5

FOR DISCUSSION:

. The differences between heated tube blow molding and extruded parison blow molding
. The effects of blow molding on the economy of industry
. The different styles of extrusion machines as they apply to blow molding

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Develop methods and equipment for blow molding on a plunger type injection molding machine.
. Develop a transparent mold which can be used to show the blowing technique.
. Try slip casting molds.

Blow Molding
courtesy of The Society of the Plastics Industry, Inc.

BLOW MOLDING

BRIEF DESCRIPTION OF PROCESS:

In the process of blow molding, a soft plastic tube (or parison) is placed between two female mold halves sealing one end, and air pressure is injected into the other end, blowing the soft plastic into the shape of the mold.

In this demonstration, a stock plastic tube is heated and placed between two mold halves and inflated. It can be called the "heated tube" method.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

- Stock plastic tubing, such as butyrate, polyethylene, vinyl, etc.
- Compressed air source
- Pair of female molds with aligning pins
- Clamping or holding device for molds
- Heater or oven, controllable to at least 450°F, for heating the plastic tube

LESSON OUTLINE:

I. Select and prepare the mold

A. Mold materials. A mold may be made from any material which will provide a suitable molding surface and will hold its shape under low heat and pressure. It should not break from clamping fixture strain. Four materials are most commonly used:
- Plaster or gypsum cement
- Wood
- Metal
- Reinforced plastics

B. Mold construction. Molds may be made similar to those used for ceramics slip casting or similar to the mold halves used for vacuum cavity forming. A wood flask or frame surrounding the plaster or gypsum cement will add strength and prevent chipping the edges. Hardware, such as that used on a suitcase, may be attached to facilitate rapid closing. Review the mold making lesson.

II. Prepare the materials

A. Preheat heating device

B. Cut plastic tubing to length

C. Air supply
- Build up air pressure
- Attach air hoses
- Attach air regulator and set to zero
- Attach air line adapter to plastic tube

D. Lay mold halves out face up next to each other

E. Adjust clamping devices to mold thickness

III. Procedure for molding

A. Heat plastic tube in oven or heater, rotating it as it is heated. (See manufacturer's specs. for proper temperature.)
B. Remove from oven or heater
C. Attach air hose to air adapter
D. Place heated tube over one mold half
E. Close mold and clamp securely
F. Adjust air regulator until plastic fills the mold; use as low a pressure as possible
G. Allow plastic to cool
H. Open the mold and remove blow molded part
I. Trim off flash and neck

IV. Alternate method (sheet plastic)

A. Construct molds as before
B. Cut two sheets of plastic to proper size (Develop a template pattern)
C. Heat plastic in oven
D. Place both sheets over one half of the mold
E. Insert a blowing tube between plastic sheets
F. Close and clamp mold
G. Blow the part
H. Cool, remove, and trim

SUMMARY:

Blow molded plastic products can be made by this method from simple, matched, gypsum cement molds. Caution should be exercised in aligning and clamping the molds to prevent misaligned parts.

QUESTIONS:

Q: How does the heated tube method of blow molding differ from extrusion blow molding?
Q: What is a simple alternate method to the heated tube blow molding method?
Q: Name several materials which can be used for mold making in heated tube blow molding.

UNIT II MOLDING AND FORMING

Lesson 10

Related Lesson: Compression molding

OBJECTIVES:

- To develop a knowledge of the history and importance of compression molding
- To develop an understanding of the materials used in this process
- To acquaint the students with the products and occupational opportunities pertaining to this phase of the plastic industry

REFERENCES:

1.	Cope, Dwight	Cope's Plastics Book	pp. 25-26
2.	Dearle, Denis A.	Opportunities in Plastic Careers	pp. 56-57

FOR DISCUSSION:

- Compression molding's place in the total plastics industry
- Variables encountered in the process
- Compounds best suited for compression molding
- Consideration of machines and equipment, types, sizes, etc.

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

- Compare volume of materials used with that of other processes.
- Compare compression process with injection molding; note difference. Look up other job possibilities (other than those mentioned).

Compression Molding
courtesy of The Society of the Plastics Industry, Inc.

BRIEF DESCRIPTION OF PROCESS: (Ref. #5)

Compression molding is a technique of thermoset molding in which the molding compound (generally preheated) is placed in the mold cavity, the mold is closed, and heat and pressure are applied until the material has cured.

MATERIALS, EQUIPMENT, AND/OR TEACHING AIDS:

. Simple mold drawing
. Chart showing halves of four molds and label
. Examples of products made by compression molding (distributor cap, dishes, electrical components)

LESSON OUTLINE:

I. History (Ref. #3)

A. The compression molding process was used for rubber molding by Thomas Hancock in the early 19th century

B. First patent on process issued to John and Isaiah Hyatt in the 1890's

C. Bakelite developed by Leo F. Baekeland
- Discovery of phenol-formaldehyde in 1908
- Need for further development

II. Material Properties

A. Thermosetting materials
- Heat of 300 degrees F (plus or minus 20 degrees) needed for curing
- Formaldehyde gas and water vapor given off

B. Size of product limited by size and tonnage of press (12 to 2000 tons)

C. Final product, a hard, heat-resistant material
- Chemical change takes place
- Cannot be replasticized by heat

D. Important variables
- Temperature of mold, material
- Pressure range
- Curing time (2-45 minutes)

III. Compounds: Resins and other materials (Ref. #2 and #3)

A. Resins
- Enough for flow and cementing (50%)
- Bulk factors (Determine by the ratio of the volume of the raw material to the volume of the cured material)
- Phenol-formaldehyde used first (1908)
- Others common to process
  a. Melamines - dinnerware
  b. Ureas - buttons
  c. Alkyds - dielectric, connector knobs, T.V.

B. Other materials
- Fillers
  a. Increase bulk, reduce cost, add heat resistance
  b. Types: wood flower, cut canvas, asbestos, shirt stock, glass fiber, thread, etc.
- Plasticizers
  a. Increase flow
  b. Change character of finished article
- Pigments add color
- Lubricants give release and flow qualities

C. Conditions of compound
- Granular or powdered
- Preforms (Measured amount of material compressed into a form on a separate machine)
- Preheated preforms (before compressing)
  a. Shortens cycle
  b. Larger articles; less pressure

IV. Presses (Ref. #2)

A. Types
- Vertical
  a. Automatic, semi-automatic, or hand
  b. Platen moves up or down on compression stroke
  c. Usually controlled electrically
- Rotary
  a. Automatic or semi-automatic
  b. Rotary movement of main parts

B. Power
- Pressure usually hydraulic - water or oil
- Heating - electrical or steam
- Controlled electrically

V. Molds (Ref. #5)

A. Material - high grade steel, for polishing and hardening

B. Types of molds
- Flash mold (widely used)
  a. Relief around cavity; lower and upper part
  b. Easy to open
  c. Easy to measure charges
  d. Lighter weight
  e. Less uniform pressure on material
  f. Needs low bulk-factor material
  g. Needs longer cure time
- Positive mold
  a. Uniform pressure on material, uniform product
  b. Uniform color of product
  c. Higher bulk-factor material can be used
  d. Shorter cure time required
  e. Requires more daylight
  f. Harder to open
  g. Heavier
  h. More accurately sized charges necessary

- Relief positive mold (landed mold)
  a. A positive mold which has been relieved to allow excess material to escape without loss in uniform pressure on material
  b. All advantages of positive mold
  c. Charges need not be weighed accurately
- Semi-positive mold (landed mold)
  a. A cross between the flash mold and positive mold
  b. Has the advantages of a positive mold except
     . Uses lower bulk-factor material
     . Uses higher flow number material
  c. Has advantages of flash mold except
     . More costly to make
     . Harder to open

C. Design considerations
- Freedom from undercut or reverse draft
- Sufficient draft on side walls
- Proper parting line
- Types of machine to be used on
- Stripper plates or ejection pins
- Temperature and pressure used in molding
- Provision to vent trapped air

VI. Consumer economic considerations

A. Compression molding about 15 percent of total plastics industry

B. Products
- Pot and pan handles - heat
- Electric iron handles - heat
- Distributor caps - electrical
- Dinnerware - durable
- Buttons - colorful, durable

C. List price on materials high
- Raw material cost high
- Production cost high

VII. Industrial considerations

A. Advantages
- Hard, dense product
- Heat resistant product
- High dielectric strength
- Relatively low cost of raw materials

B. Disadvantages
- High cost of molds
- Long cure cycle
- Material waste (cannot be reused as in injection molding of thermoplastics)

VIII. Guidance (Ref. #6)

A. Occupation - press operator
- No experience, training 2-3 weeks
- Physical - none
- Duties - vary with machine

- Working conditions - heat, noise
- Hazards - blowing excess materials; hot machines and materials
- Goggles are usually required

B. Accidents - very few disabling injuries

C. Pay scale, 1963
- Molder - $1.91 - $2.48
- Learner - $1.50 - $1.91
- Set up man - $2.00 - $2.20

SUMMARY:

In compression molding, thermosetting materials are generally used. The temperatures, pressures, and curing times depend largely upon the machinery available and upon the compounds used. The resulting product is hard, dense, and has heat resistant properties which cannot be obtained by other plastic molding methods.

QUESTIONS:

Q: What kinds of materials are used in compression molding?
Q: Why are filler materials used in the compound?
Q: What are compression molds made of?
Q: What are preforms, and why are they used?

Various Types of Compression Molds

UNIT II MOLDING AND FORMING

Lesson 11

Demonstration: Compression molding

OBJECTIVES:

. To show the student the compression molding process
. To acquaint him with the machine and equipment used
. To develop further understanding of the materials used for compression molding

REFERENCES:

1. *Carver, Fred	Carver Press Booklet	All
2. SPI	Plastic Engineering Handbook	pp. 11-16
3. SPI	Plastics: The Story of an Industry	pp. 14-22
4. Phillips Chemical	Glossary of Plastics Terms	p. 7
5. *Winding, C. Charles	Polymerc Materials	

FOR DISCUSSION:

. Semi-automatic and automatic machines, and molds for these machines

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Mold a set of checkers or coasters.
. Fabricate a window scraper.
. Test materials, mold using different temperatures, pressures, and times.

BRIEF DESCRIPTION OF PROCESS: (Ref 2)

Compression molding is a technique of forming thermosetting materials. The molding compound (generally preheated) is placed in the mold cavity; the mold is closed, and heat and pressure are applied until the material has cured.

MATERIALS, EQUIPMENT, AND/OR TEACHING AIDS:

. Compression molding or laminating machine
. Mold for desired article
. Materials
  a. Plastic resins: melamine, phenolic, urea
  b. Fillers: wood flour, asbestos, chopped rag, glass fibers, etc.
  c. Pigments: tempera colors, commercial colors
. Gloves, asbestos
. Spoon or other device for loading mold
. Chart: Plastic Properties, Part II, (thermoset), Modern Plastics Encyclopedia

LESSON OUTLINE:

I. Using a press for hand molds 10 to 30 tons (Ref 1)

A. Platens - Plates that squeeze mold halves together (horizontal member)
- Size varies with press
- Heating plates fastened to platens
- Bottom platens usually movable; top may be also

B. Ram - Transmits pressure from hydraulic mechanism (jack) to platens (Ref 2)
- Vertical movement
- Pressure is applied to either upper or lower plates (usually the lower plate)

C. Columns (Vertical Structural Members)
- Adjust for daylight between platens
- Platens to be in parallel alignment

II. Mold (See related lesson.)

A. Flash
B. Positive
C. Relief Positive
D. Semi-Positive

III. Materials

A. Resin
- Types - phenolic, urea, melamine
- Temperature range 275° to 350°
- Comprises 50% of total compound

B. Filler
- Types - glass fibers, wood flour, (from disc sander), asbestos, chopped rag
- Comprises about 45% of compound

C. Pigments about 5% - tempera color, etc.

IV. Preparation of compound

A. Measure and mix components
B. Prepare charge; measure correct amount

V. Molding operation

A. Preheat press platens to 300° F
B. Place mold on lower platen with upper mold or plunger removed
C. Allow molds to preheat
D. Place prepared charge in cavity
E. Place upper mold force in position and close press slowly, allowing gases to escape
F. Press pressure is determined by multiplying surface area in square inches by the proper compression molding pressure factor. This factor is given in pounds per square inch (psi) in the Modern Plastics - Plastics Properties Chart
G. Release molding pressure; remove mold; remove object from mold

VI. Finishing:

A. Remove flash by sanding, tumbling, or grinding, or break off by hand
B. Buff or polish if necessary

VII. Safety:

A. Wear gloves when near heated areas
B. Wear goggles during the compression holding cycle

SUMMARY:

A variety of articles can be produced by compression molding with a simple hand mold, a common thermosetting plastic material, and the proper application of heat and pressure. The machines and materials used in industry may vary considerably from the ones used in this demonstration, but the basic process of compression molding is the same. An industrial laboratory press works well.

QUESTIONS:

Q: What function do the platens serve on a compression molding press?
Q: What mechanical features are found on an automatic compression molding press which are not found on hand presses?
Q: Why are filler materials added to the resin for compression molding?
Q: What is the curing temperature range of most of the materials used for compression molding?

UNIT II MOLDING AND FORMING

Lesson 12

Related Lesson: Transfer molding

OBJECTIVES:

- To develop in the student an understanding of the transfer molding process
- To acquaint the student with the materials and equipment used in transfer molding
- To give the students an understanding of the relationship of transfer molding to compression and injection molding

REFERENCES:

1. *Gerbracht, and Robinson	Understanding America's Industries	p. 138
2. *Winding and Hiatt	Polymeric Materials	p. 119
3. Simonds and Church	Concise Guide to Plastics	pp. 117-172
4. SPI	Plastics Engineering Handbook	Chap. 4 p. 8

FOR DISCUSSION:

- Process description (no demonstration)
- Comparison with compression and injection molding
- Encapsulating process

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

- Show advantages of transfer molding over compression molding.
- List some common household products made by this process.
- Make a simple mold for use in a compression press.

Transfer or Plunger Molding
courtesy of The Society of the Plastics Industry, Inc.

BRIEF DESCRIPTION OF PROCESS (Ref 2):

Transfer molding is a process whereby a dry, solid molding compound (thermoset) is heated in a separate chamber to the point of plasticity, and then forced (transferred) under pressure into a heated, closed mold, by means of an hydraulically operated plunger. (See third objective of this lesson.)

MATERIALS, EQUIPMENT, AND TEACHING AIDS:

. Blackboard drawing or chart of a pot-type mold and plunger mold
. Samples of products:
  - Distributor cap
  - Flat iron handles
  - Handles for pots and pans
  - Encapsulated electronic devices - Resistors

LESSON OUTLINE:

I. Limitations of compression molding precluded (Ref 4)

  A. Molding of articles with intricate sections
  B. Molding of articles with thin walls
  C. Molding articles with fragile inserts

II. Detailed description of process: (Ref 4)

  A. Types of transfer molding
    - Pot-type (Explain by using equipment)
    - Plunger (chart or board, Ref 1 & 2)

  B. Material in powdered or preformed condition

  C. Preheated (Radio frequency heating) to semiplastic state

  D. Introduced into pot chamber separate from mold cavity

  E. Material forced or transferred through orifice to heated, closed mold

  F. Allowed to cure in mold with heat and pressure

III. Differs from compression molding (Ref 3)

  A. Material is not loaded directly into mold cavity
  B. Material is forced into mold in semiplastic state
  C. Thorough preheating is necessary

IV. Differs from injection molding

  A. Only enough material is heated for one cycle
  B. Sprue is reversed to keep it attached to cull (excess material in pot)
  C. Curing is continued by heat and pressure, not by cooling

V. History and Development (Ref 4)

  A. First press developed in 1926 by Shaw Insulator Co.
    - Single ram compression molding press
    - Mold especially designed for pot-type transfer molding
    - Material was preheated in separate oven

B. Double ram presses
- Main ram attached to lower platen
- Auxiliary rams forced material into cavity (plunger molding)
- Rams could be side mounted

C. Introduction of new preheating methods
- Accelerated during and after World War II
- Steam and high frequency dielectrics used
  a. Speeds of cure increased
  b. Lower pressures for transfer and clamping resulted

D. New Automatic Presses 1956
- Horizontal, using loose powder and inexpensive molds
- Vertical press
  a. 400 ton clamping capacity
  b. Extremely fast
  c. Designed for preheated preforms

VI. Materials

A. Phenol-formaldehyde
  a. Flows easily in molding
  b. Forms dense molded articles
  c. Limited colors - blacks and browns

B. Melamine
  a. Requires some property change for best flow
  b. Good color - full range shades and colors
  c. More difficult to mold than urea and phenolic
  d. Ease in preheating
  e. Higher priced than phenolic; 15% more than urea

C. Epoxies
  a. Newest material used
  b. Ease of being formulated into semi polymerized stage

D. Urea
- Full color range; stable in sunlight
- Double the price of phenolic
- Requires 50 percent higher holding pressures than phenolic

VIII. Pressures for molding (Ref 3)

A. Mechanical pressure on molding material in psi

B. 10 to 15 percent more clamping pressure than transfer pressure, to prevent flashing

C. Pressures vary with design of mold and material used as in the following examples:
- Phenolic material preheated-8000 psi plunger type and 12,000 psi pot-type
- Fabric-filled phenolic materials, 50 percent increase in transfer pressure required

IX. Encapsulating (by transfer molding)

A. General definition of encapsulating - Enclosing an article (usually electronic components) in a closed envelope of plastic

B. Advantages over encapsulating by compression molding:
- Better density of finished product
- Greater mechanical strength
- Less waste due to breakage
- Faster than casting methods

X. Limitations of transfer molding

A. Cost of making molds many times higher than compression molds because of intricate detail

B. Loss of material in cull, gates, and runners; cannot be reused

C. Strength sometimes reduced

D. Temperature critical; must keep materials from total polymerization

SUMMARY:

Transfer molding is becoming very widely used for thermosetting plastic materials because more intricate, thin-walled articles can be made. Many products used in the electrical industry are now being encapsulated by the transfer molding process. With better thermosetting materials being made, the future of transfer molding looks bright.

QUESTIONS:

Q: What types of materials are used in transfer molding?
Q: Transfer molding is related to what two other molding processes?
Q: Why is it necessary to preheat the material for transfer molding
Q: What new material has very recently been successfully used for transfer molding?

UNIT II MOLDING AND FORMING

Lesson 13

Related Lesson: Thermoforming

OBJECTIVES:

- To acquaint the students with the thermoforming process
- To develop an understanding of the industrial uses of thermoforming methods
- To create an awareness of the many practical uses of the thermoforming methods of packaging and fabrication
- To convey to the student the impact thermoforming has had on industrial fabrication

REFERENCES:

1.	Butzko, R. L.	Plastics Sheet Forming	
2.	Cherry, Raymond	General Plastics Revised 1964	Ch. 19
3.	Edwards, Lauton	Industrial Arts Plastics	pp. 37-41
4.	Simonds and Church	Concise Guide to Plastics	pp. 1-12, 182-194
5.	SPI	Plastics Engineering Handbook	pp. 91-117
6.	Swanson, Robert	Plastics Technology	Ch. 8
7.	Vol 39 #1A	Modern Plastics Encyclopedia	pp. 737-39
8.	Wenberg	"Vacuum Forming Unit" School Shop, March 1963	

FOR DISCUSSION:

- The diversification of thermoforming methods
- The common applications of thermoforming methods
- What thermoforming has done to enhance other industries
- New developments in the thermoforming industry

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

- List the uses of thermoformed products.
- Compare thermoformed products to similar products molded by other processes, including injection, rotational, and blow molding.
- Have students relate other possible uses for thermoformed products.
- Use various materials to make molds for vacuum forming and compare product quality.

BRIEF DESCRIPTION OF PROCESS:

Thermoforming is a method of forming plastic sheets which utilizes the ability of plastic to be shaped immediately after it has been heated to a plastic state. After the plastic sheet has been formed it is allowed to cool while it is still on the mold, thus retaining the shape of the mold.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

- Samples of thermoplastic sheets (polystyrene, cellulose acetate, polyvinyl chloride, ABS, cellulose acetate, butyrate, and others)
- Samples of thermoformed products (Bubble pack, free blow, skin package, etc.)
- Wall chart showing the different types of thermoforming
- Examples of different molds (cavity, drape, and stretch)

LESSON OUTLINE:

I. Thermoforming methods and Typical Applications

A. Vacuum cavity forming	Refrigerator door liners
B. Drape vacuum forming	Counter displays
C. Male form forced above the sheet	Deep draw trays
D. Vacuum snap back forming	Hobby horses
E. Plug and ring forming	Skylight domes
F. Air pressure forming	Candy dishes
G. Matched mold forming	Boat Hulls
H. Mechanical stretch	Stiff or thick sheets

II. Scientific principles in thermoforming

A. Vacuum forming. The removal of air from the mold side of the thermoplastic sheet causes atmospheric pressure (14 to 15 psi) to push the heated plastic against the mold. (air pressure differential)

B. Pressure or blow forming. Air pressure (also mechanical pressure, alone or in combination) is applied to the plastic on the side away from the mold to overcome the atmospheric pressure and force the plastic against the mold. (air pressure differential)

C. Heat effect on thermosplastic. Heat absorbed by the thermoplastic causes it to soften because the molecular bond within the plastic loosens (molecules become more active), allowing the plastic to become formable. Cooling the plastic tightens the bond (molecules become less active), making the formed plastic rigid.

III. Application

A. Packaging. Applications range from the vacuum forming of squeeze tubes for caulking compound to boilable bags for frozen foods.

B. Fabrication. The uses range from swimming pools to factory building panels.

IV. Advantages and disadvantages

Manufacturers have frequently found that for short production runs the thermoforming processes are practical. Large items that would be impractical to mold by other methods may be thermoformed. The cost of plastic sheet is high compared to the lower cost of the pellets for injection molding. When the job run is not long enough to pay for the necessary dies used for injection molding, thermoforming processes may be employed.

V. Industrial considerations

A. Appropriate use: Where short run or high mold costs dictate
B. Cost: High sheet cost; low mold cost
C. Change: Products Can be redesigned or revised as needed
D. Equipment: Lower cost fabrication equipment. Cost range for machine, $40 to $5,000 (Many custom built)
E. Personnel: Duration of training period varies with job

VI. Guidance

A. Rapid growth; since 1950, especially in the field of packaging of produce and other products
B. Sales managers - A good future in promotion and sales
C. Tool and die makers - high pay rate
D. Millwrights - high pay rate
E. Machine operators - Low pay rate due to minimal training required
F. Patternmakers - high pay rate

SUMMARY:

Thermoforming as a phase of the plastics industry has experienced a period of rapid growth. The great gains in this area seem to have come in the packaging industry. It has been found that thermoforming may be used economically for fabrication of short runs of unusual shapes.

QUESTIONS:

Q: What is meant by thermoforming?
Q: List the different methods of thermoforming.
Q: Why have the packaging industries turned to skin packing?
Q: Name the chief material used for the thermoforming process.
Q: What three scientific principles are involved in the thermoforming processes?

BASIC TECHNIQUES FOR THERMOFORMING SHEET

1. STRAIGHT VACUUM FORMING

2. DRAPE VACUUM FORMING

3. FORCE ABOVE SHEET

4. VACUUM SNAP-BACK FORMING

5. PLUG and RING FORMING

6. FORMING INTO FEMALE WITH HELPER AND AIR PRESSURE

7. PRESSURE FORMING

IN THESE SIMPLIFIED schematics of seven basic methods, letters indicate the following: A = Heater; B = Clamp; C = Plastic Sheet; D = Mold; E = Vacuum Line; and F = Air-Pressure Line. The methods (fully described in the text) are as follows: 1) Straight vacuum forming. Clamped in a stationary frame, the heated sheet is vacuum drawn into the mold. 2) Drape vacuum forming. Moveable frame or clamp drapes the sheet, softened by heat, over male mold before vacuum is pulled. 3) Force above sheet. Mold descends onto heated sheet, partially forming it; then the vacuum is pulled. 4) Vacuum snap-back forming. Vacuum is pulled, drawing pre-heated sheet into cavity G. Male plug moves down until it reaches a predetermined position. Vacuum is then applied through male plug. 5) Plug and ring forming. Heated sheet is placed over a ring and clamped down. Mold mounted on ram is forced into it. 6) Forming into female with helper and air pressure. As press closes, cored plug pushes heated sheet into cavity. Air pressure, introduced through plug, pushes sheet into female mold. Holes in mold let air escape. 7) Pressure forming. After heating, framed sheet is formed between matched male and female dies.

courtesy of Modern Plastics Encyclopedia

UNIT II MOLDING AND FORMING

Lesson 14

Demonstration: Thermoforming

OBJECTIVES:

. To demonstrate different thermoforming methods

. To create an awareness of the many practical uses of thermoformed products

. To develop safe working habits while in the thermoforming area

FOR DISCUSSION:

. Various heat application methods
. Visual conceptions of thermoforming methods
. Practical applications of thermoformed products

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Have the students experiment with the different methods of thermoforming plastic.
. Have the student originate a project.
. Report on thermoformed products and their probable forming methods.

Straight Vacuum Forming
courtesy of Modern Plastics Encyclopedia

SSI 121

BRIEF DESCRIPTION OF PROCESS:

Thermoforming is any process of forming thermoplastic sheet which involves heating the sheet and stretching it to conform to a mold. After the plastic has been formed it is allowed to cool while it is still on the mold, thus retaining the shape of the mold.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

- Polystyrene, cellulose acetate, butyrate, ABS, and other thermoplastic sheets
- Cavity drape and/or blow molds (soap dish, wall plaque, planters, candy dishes, etc.)
- Vacuum and/or compressed air - source vacuum cleaner, air compressor, converted piston type refrigerator pump, milking machine vacuum pump, commercial vacuum units, etc.
- Heat source for plastic sheet (domestic baking oven, commercial oven, radiant heater, heat lamps, etc.)
- Thermoforming machine (commercial or teacher-made)
- Skin packaging card backs

LESSON OUTLINE:

I. Select material to be used

A. Polystyrene (preferred material, lowest cost)
B. Cellulose acetate
C. Cellulose acetate butyrate
D. ABS
E. Others

II. Prepare stock to be molded

A. Cut to proper size

B. Clamp in holding device

C. Heat to proper temperature for forming
- Set oven control to proper temperature
- Judge visually, by the amount of sag and/or the amount of smoke

III. Form the prepared plastic sheets

A. Vacuum cavity - apply vacuum
B. Drape - apply vacuum
C. Blow - start from zero pressure, apply pressure slowly

IV. Cool until rigid, cool to the touch

V. Finish

A. Remove from the mold

B. Trim off excess stock
- Jig saw or band saw
- Router, or a router blade in a drill press

C. Finished edges, if necessary, by filing, sanding, and/or buffing

122

VI. Molding Tips

A. Be sure you have a good vacuum or pressure seal on mold and plastic

B. Check molds for damage or lack of preparation

C. Have the plastic sheets at the proper temperature before attempting to form them. (Check specifications)

D. When more than one item is to be formed on one sheet, be sure the spacing is correct. If the molds are too close together, a web will form between them.

E. If the first attempt at forming fails, remember that you are using a thermoplastic sheet. It may be reheated and reused.

VII. For safety, handle hot plastic with gloves

SUMMARY:

In the thermoforming processes, three scientific principles are involved. First, vacuum forming uses atmospheric pressure (14-15 psi) to press the plastic to the mold, after the pressure is decreased under the mold. Second, increased air pressure on one side of the plastic sheet overcomes the atmospheric pressure on the other side and forms the plastic onto the mold. Third, the application of heat causes the molecular bond within the thermoplastic sheet to loosen, allowing it to be formed. Cooling restores the original molecular bond.

QUESTIONS:

Q: How can you tell when the plastic sheet is ready to mold?
Q: What happens when there is a poor seal between the sheet and the mold?
Q: Must you scrap a sheet which is malformed on the first try?
Q: What is a web, and why does it occur?
Q: What is thermoforming?

UNIT III MOLDMAKING

Lesson 15

Related Lesson: Moldmaking

OBJECTIVES:

- To acquaint the student with procedure in moldmaking
- To develop an understanding of the importance of proper mold fabrication
- To explain the methods of fabricating gypsum cement, epoxy, and metal molds
- To explain the reasoning and methods used in arriving at the selection of certain types of molds

5.	Swanson, Robert	Plastics Technology	ch. 14

FOR DISCUSSION:

- Mold design considerations
- Mold making, the heart of the plastics industry
- Advantages of each type of mold
- Types of mold in relation to material to be molded
- Type of mold in relation to molding process

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

- Fabricate molds for vacuum forming, injection molding or compression molding.
- Repair damaged molds.
- Develop a chart for moldmaking showing different types of molds and their uses.
- Do research concerning moldmaking.

BRIEF DESCRIPTION OF PROCESS:

A mold is a device into which, or onto which, plastic materials are placed to cure or harden them by heat, cooling, and/or pressure, thus forming a molded part or article. Three materials often used for molds in the plastics industry are: gypsum cement, epoxy resins, and metals. Others would include plastics, wood, glass, and ceramics; however, these last four are in very limited use. The length of the production run, the pressures involved, the size of the molded product, and the heat required determine the design, method, and material for mold making.

MATERIALS, EQUIPMENT, AND/OR TEACHING AIDS:

- Samples of different molds or patterns
- Gypsum cements, epoxies, and metal mold blanks
- Samples of molds made of different materials
- Wall charts of mold types

LESSON OUTLINE:

I. Mold design (refer to reference #3, pp. 88-90, and #5, ch. 14)

A. Terms to know about
- Male and female molds
- Matched molds
- Draft and undercuts
- Strength of materials used
- Finish
- Protective coatings

II. Gypsum cements molds

A. This type of mold is made of plaster or gypsum cement poured over a model or pattern of the desired shape
- Plaster, known as a "soft mold" in industry will not stand up to rough use but may be used for models or prototypes
- Super-strength gypsum cements have proved much more rugged in nature and will take more punishment

B. Application of gypsum cement molds
- Mass cast; material is poured over the object to form the basic shape
- Surface cast; material is applied to the surface of the model or pattern and backed up by a reinforcing material, such as, burlap, wire or other supportive materials
- Frame and wire; basic shape is formed by a gypsum cement. It is spread on, to give a finished shape (sometimes called "loft" method)

C. How gypsum cement molds are made (mass cast)
- Flask or form (wood or sheet metal frame)
- Pattern or model types
  a. Wood models (mold released)
  b. Vacuum formed sheet
  c. Metal objects
  d. Plaster models (mold released)
- Preparation of the mold
  a. Should be cleaned and/or polished
  b. A mold release agent must be used on porous surfaces and on aluminum

- Mixing gypsum cement; should add water until desired consistency is achieved
- Pouring gypsum cement; should be done at a steady, even rate so that there will be little or no air trapped
- Jiggling; done by gently shaking the form or flask
  This action releases any air bubbles that may have formed around the model or pattern

D. Industrial considerations (gypsum cement molds)
- Advantages:
  a. Easy to fabricate
  b. Fabrication cost is low
  c. Easily repaired
- Disadvantages:
  a. Short pot life
  b. Easily damaged
- Amount of use in industries:
  a. Limited at present
  b. Growing with experimental improvements

III. Epoxy resin molds

A. Epoxy resin is a clear liquid resin that is formed into a solid by a chemical reaction. The chemical reaction is caused by a hardener. Epoxy resins have high strength, heat resistance, shock resistance, and easily adhere to other materials.

B. How epoxy resins are used in moldmaking
- As a single material
- Combined with other materials such as metal, fiber glass, wood flour or chips, and other materials to take up volume
- Mixed with special materials to change strength and heat resistance
  a. Metal filled for increased shock resistance

C. How epoxy resin molds are made
- Mass cast. A model is either a male or a female form; epoxy resin is poured over it to form a die or mold.
  a. Use of mass cast dies. They may be used for drawing, forming, bulging, or injection molding.
  b. Mass casting procedure
     . Apply mold release to model or pattern
     . Mix epoxy resin with required hardener
     . Pour over the mold
     . Cure at room temperature or oven heat
- Surface casting. An epoxy resin surface is applied to a rough cast backing, using a model or mold to form the working surface
  a. Pour method. Core suspended over die mold and then sealed. Epoxy resins are then poured through the predetermined opening.
  b. Squash method. A paste of epoxy resin is placed on the die mold. The core is then placed on the material and allowed to settle to a predetermined position.
  c. Pressure pot method. Epoxy resin liquid is forced into a die that has been sealed. This is accomplished by forcing the material in at the low points and venting at the high points.

- Industrial considerations (epoxy resin molds)
  a. Technical advantages
     . Light weight and easily handled
     . Damage is easily repaired, thus lowering break down time
     . Bondable to almost any material
  b. Disadvantage: Limited to job runs of 50,000 items or less
  c. Cost
     . Reduces tooling time by 50 percent
     . Reduces delivery time for dies by 70 percent
     . Fabricated at one half of cost metal dies

IV. Metal molds

A. Types
- Machines. Fabricated from blocks of cold-rolled steel, tool steel, die steel, etc.
- Cast. From steel, aluminum etc.
- Spun. Generally from a non-ferrous metal
- Hobbed. Same material as machined molds
- Electroformed. Nickel the most popular material for this mold
- Low-melting alloys

B. Applications
- Machined molds for injection, compression, and transfer molding
- Cast molds for thermofusion, expandable beads, and rotational molding
- Spun molds for forming or bulging dies
- Hobbed for compression or injection molding
- Electrochemical machining for a wide variety of molding processes
- Low-melting alloys for prototypes

C. Fabrication of metal molds
- Machined. Using general tool room machinery
- Cast. Using general foundry procedure with special sand; also using pressure casting methods
- Spun. Using general rules of metal spinning
- Hobbed. Male die is pressed into mold blank under high pressure
- Electrochemical machining. Metal eroded by arc to duplicate carbon die
- Low-melting alloys. Softer material for short runs

D. Finishing metal molds
- Chrome plated and then polished
- Epoxy resin faced
- Teflon-coated working faces

E. Industrial considerations
- Machined molds. The most widely used because of durability and dependability
- Cast molds. A practical method for forming expandable beads
- Spun molds of limited use though not uncommon
- Hobbed molds
  a. Where multiple identical cavity molds needed
  b. Where internal milling is difficult but external milling is easier (small knobs, etc.)

OCL 129

V. Other methods of moldmaking

A. Wood forms
B. Ceramic molds
C. Reinforced plastic
D. Elastomer RTV

SUMMARY:

Moldmaking is said to be the heart of the plastics industry. The considerations in the fabrication and selection of molds are critical. The poor selection of a mold by a processor might prove costly to him. There are three main types of molds used in the plastics industry today. The plaster or soft molds, the epoxy resin molds, and the metal molds. Each has its own place and purpose in the plastics manufacturing industry of today.

QUESTIONS:

Q: What are the main considerations in mold design?
Q: What is a soft mold, and what are its basic material ingredients?
Q: What are epoxy resins?
Q: What is the most widely used mold material in the plastics industry?
Q: What types of materials require the use of mold release when you are making a mold?

Mold Design Considerations

UNIT III MOLDMAKING

Lesson 16

Demonstration: Moldmaking

OBJECTIVES:

. To show the proper method of fabricating a gypsum cement mold

. To show the proper method of fabricating an epoxy resin mold

. To develop an appreciation of proper mold design

REFERENCES:

1. Cherry, Raymond	Gen. Plastics 4th Ed.	Chap. 24
2. *Skiest, Irving	Epoxy Resin	pp. 18-20
3. SPI	Plastic Eng. Hand Book	pp. 199-204,220
4. Steele, Gerald	Fiber Glass - Projects and Procedures	pp. 39, 88-90
5. Swanson, Robert	Plastics Technology	Chap. 13-14

FOR DISCUSSION:

. Considerations in mold design
. Determining the right mold for the job
. The importance of molds to the industry
. Advantages of each type of mold

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Design a model or pattern for a mold.
. Fabricate a mold from a students design.
. Repair a damaged mold.

BRIEF DESCRIPTION OF THE PROCESS:

Moldmaking is the heart of the plastics industry today. The success or failure of a job depends on the selection of the proper mold or die for the work to be done. Molds may be made of many different materials and by many different processes. High strength, gypsum cement and metal-filled epoxy molds are types which can be made in the school shop without extensive equipment. Yet these two materials provide opportunities for extensive moldmaking and for the investigation of many plastics processing methods.

MATERIALS, EQUIPMENT, AND/OR TEACHING AIDS:

. Room-temperature and oven-curing epoxy resins, filled and unfilled types (Ren, Devcon, etc.)
. Plaster and gypsum cement (Hydrocal, ultracal, etc.)
. Models or patterns (wood, metal, plastic, glass, plaster, etc.)
. Flasks or forms (wood, metal, etc.)
. Scale (pounds and ounces)
. Mixing containers (paper cups, metal cans, etc.)
. Mixing sticks (coffee stirring sticks, tongue depressors)

LESSON OUTLINE:

I. Gypsum Cement Molds

A. Preparing flask
- Check for proper construction (reference #3, pp. 199-204, #5, Ch. 13-14)
- Seal the seams to prevent leaks

B. Preparing model or pattern
- Coat with a mold release (appropriate for mold material)
- Set the model in the proper position in the flask and secure it

C. Mixing gypsum cement. (Manufacturer's directions should be followed in attempting to mix gypsum cement; general procedure outlined below.)
- Water and plaster or gypsum cement are weighed separately before mixing to obtain correct consistency
- Sift the plaster or gypsum cement into the water. Allow to stand for 1 to 3 minutes; then mix thoroughly.
- Stir until mixture reaches a creamy state. Failure to mix properly will result in a dense mold face or pinholes. Avoid mixing air into the plaster.

D. Pouring
- Start pouring at one end of the flask and pour at a steady even rate until it flows into an even layer
- Draw a coarse file the wrong way over the edge of the flask. The gentle vibration will cause the entrapped air bubbles to rise to the surface. Tapping lightly will also assist in removing air bubbles.

E. Curing gypsum cement molds
- Allow 30 to 60 minutes for cement to set before removing the model or pattern. (See manufacturers instructions.)
- Allow the mold to thoroughly air-dry for at least 48 hours before use

F. Finishing. An appropriate finish may be applied to the surface, depending on the end use.
- Lacquer - vacuum or pressure forming
- Plastic resin - reinforced plastics
- Wax - most used

II. Epoxy resin molds (Read thoroughly the manufacturer's instructions for exact directions and proportions.)

A. Prepare flask or form
- Select either the flask or the form to be used. (Check reference #4, pp. 199-204, Ref #5, Ch. 14.)
- Coat with a mold release

B. Prepare model or pattern
- Model or pattern must be completely free of moisture
- Coat model or pattern with mold release
- Position model or pattern in desired place in flask
- Preheat model and flask to approximately 200° F. if an oven cured epoxy resin is used

C. Mixing epoxy resins (Use a resin appropriate to end use.)
- Measure and pour epoxy resin into a clean metal container and heat 212° F. (Direct heat is not recommended; use an oven or double boiler. (This step is necessary only when using an oven-curing epoxy resin.)
- Measure out the correct amount of hardener
- Add the hardening agent to the resin and stir well

D. Pouring
- Pour the resin into a corner of the flask slowly to prevent the trapping of air, allowing it to flow into an even layer
- Allow the mixture to cure either in the oven or at room temperature, depending on the resin type used

E. Remove the cured mold from the flask, and remove the pattern after the cure is complete

III. Metal molds

. For information on the fabrication of metal molds, refer to metal working text books and Reference #4
. See related Lesson 15 for metal mold information

SUMMARY:

The use of gypsum cement molds and epoxy molds is increasing in the plastics industry today. Advances in the development of these materials are broadening their use. These types of molds are becoming more appealing to manufacturers because of the great savings in time and money they offer, especially for short runs and/or low pressure molding applications.

QUESTIONS:

Q: What two methods may be used to cure epoxy resins?
Q: Why must gypsum cement be thoroughly mixed?
Q: Why must the containers used for mixing epoxy resin and the hardening agent be clean?
Q: Why is the use of gypsum cement and epoxy resin molds on the increase in industry today?

133

UNIT III MOLDMAKING

Lesson 17

Related Lesson: Elastomers

OBJECTIVES:

. To acquaint pupils with elastomeric materials
. To develop an awareness of their industrial applications
. To convey to the students the occupational opportunities created by elastomers in relation to occupational opportunities in the plastics industry as a whole
. To classify several important elastomers

REFERENCES:

1.	Dow Corning Co.	What's a Silicone	
2.	Horsch, M. J.	Factory Magazine	Report No. 19
3.	Meals and Lewis	Silicones	
4.	SPI	Plastics Engineering Handbook	pp. 516-517
5.	Simonds and Church	Concise Guide to Plastics	pp. 61-63

FOR DISCUSSION:

. Some flexible foams which are elastomers
. Industrial trends of elastomers

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Make up a wall chart on elastomers.
. Make up a sample display board.
. Prepare handout sheet with list of major elastomers.
. Test various kinds of elastomers for stretch qualities.

BRIEF DESCRIPTION OF PROCESS:

Plastics are divided into two broad classifications: thermoplastics and thermosets. Some elastomers are considered thermosetting and some are considered thermoplastics. Elastomers may have some properties of both thermoplastics and thermosets, and some properties which do not fall into either of these classifications. An elastomer is a material which at room temperature stretches under low stress to at least twice its length and snaps back to the original length upon release of stress.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Samples of various elastomers
. Chart or list of elastomers
. Film entitled "You and the Silicones" (16 mm sound, color, 31 min.) by Dow Corning (SPI Film Catalog)

LESSON OUTLINE:

I. Usual characteristics of elastomers

A. Flexible at extremely high and low temperatures

B. Stretch under low stress at room temperature to at least twice their length and snap back to their original length

II. Specific elastomers and their properties

A. Acrylic rubber
- Oil resistance and great flex life
- High temperature (300° F to 400° F)
- Resist oxidation and sunlight

B. Butyl rubber
- Good mechanical properties
- Resistant to sunlight and hard weather
- Stiffens sharply at low temperatures

C. Chloroprenes (neoprenes)
- Substantial fire, oil, and abrasion resistance
- Not highly affected by oxygen, ozone, or sunlight
- Very resistant to chemical action

D. Fluoroelastomers
- A rigid fluorocarbon plastic
- Good high temperature performance

E. Silicone rubbers
- Well known for their ability to remain flexible
  a. Up to high temperature of 500° F
  b. Down to extreme low temperature of - 150° F
- Applications
  a. Calking and gasket material
  b. Water repellants, clothes, bricks, etc.
  c. Polishes and car waxes
  d. Release agents - for removing part from mold
  e. Lubricants - with ball bearings
  f. Retardants - to keep fluids from freezing
  g. Defoamers - for use in reducing foam in batch mixing
  h. Aircraft ignition sealants

III. Brief history of elastomers

A. Natural rubber was first known elastomer and is used as standard of comparison for elastomers

B. Silicone the first elastomer to be produced by reduction of silicon, an abundant material in earth's surface

C. Great accomplishment in experimentation by Swedish chemist - Johann Berzelius, 19th century

D. Now used commercially as a result of work done at the University of Nottingham, England - Dr. Kippling

E. In 1930's, further development led to discovery of many uses for silicones - Dr. Hyde

IV. Industrial Processing

A. Elastomers generally are mixed in large vats
- To change the characteristics of an elastomer, different ingredients are added, such as:
  . Solvents
  . Plasticizers
  . Varnishes
  . Color additives

B. Elastomers become products through:
- Metering elastomeric material into molds
- Vulcanizing at high temperatures
- Room temperature vulcanizing (RTV)

V. Industrial considerations

A. The production of elastomers comprises about one-fifth of the total production of plastic products

B. The cost of equipment and materials is relatively higher than that involved in other processes

VI. Consumer values

A. Elastomers provide longer service life than other materials

B. Elastomers are very adaptable to customers uses or to use as a part of a finished product

SUMMARY:

Natural rubber was one of the first known elastomers. It was found that natural rubber had a stretch factor, which is an important characteristic of elastomers. Recently, many modifications of elastomers have made this material useful in numerous industrial applications.

Silicone is one of the important elastomers. It is vital to many industrial operations and to the service industries due to its flexible characteristics.

QUESTIONS:

Q: What is an important characteristic of an elastomer?
Q: Which elastomer leads in industrial uses?
Q: Elastomers belong in which general classification of plastics?
Q: What was the first known elastomer?

UNIT III MOLDMAKING

Lesson 18

Demonstration: Casting with silicone rubber

OBJECTIVES:

. To demonstrate to the student how to work with silicone elastomers

. To show how room temperature vulcanizing (RTV) materials can be used

REFERENCES:

1. *Dow-Corning	Silicones (pamphlet)	Dow-Corning Midland, Mich.
2. *Meals and Lewis	Silicones	
3. *Smith, H. A.	Making Flexible Molds (pamphlet)	Dow-Corning Midland, Mich.

FOR DISCUSSION:

. General applications of castings possible with RTV type silicones
. Future uses of this material in industrial arts
. The reason catalyst is used in RTV silicones
. The theory of cure RTV silicones

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Select a pattern for reproduction.
. Have the student make several molds, one requiring a one piece mold, one needing two piece mold, etc.

Mold Making with Silastic RTV Materials
courtesy of Dow Coming Corporation

BRIEF DESCRIPTION OF PROCESS:

RTV silicone rubber is a plastic material which, with the addition of a catalyst, cures at room temperature to form an elastomer. It can be used to make flexible molds or mold copies of objects. These molds may then be used to make castings with other plastic materials or to make other molds from silicone RTV.

MATERIALS, EQUIPMENT, AND/OR TEACHING AIDS:

. RTV silicone rubber
. Catalyst for RTV
. Measuring containers and mixing sticks
. Beam scale
. Pattern
. Flask or form

LESSON OUTLINE:

I. The use of RTV silicone rubber

A. Easy and safe to use

B. Releases readily from most materials without use of release agent

C. Reproduces fine detail

D. Will not distort with casting temperatures up to 500° F

II. Preparing the pattern (i.e., radio dials, handles, novelties)

A. Original may be made of
- Wood
- Plastic
- Wax
- Soap
- Glass
- Metal

B. Clean grease, oil or burrs from surface

C. Make sure corners, crevices, and draws are free from foreign matter

D. Use release agent only if pattern has high details or large undercuts; use as spray or dip
- Silicone spray
- Solution of household detergents made up of 5 parts detergent to 100 parts water
- 5 percent solution of xylene

III. Preparing one-piece mold

A. Place pattern in retaining flask or form
B. Allow one-fourth to one-half inch clearance on all sides of pattern in flask
C. Use release agent if complex undercuts exist

IV. Preparation of silicone RTV for pouring (Read manufacturer's instructions carefully.)

A. Place measured amount of silicone rubber into mixing cup
B. Add one-half percent by weight of catalyst, according to directions. (Other percentages may be used according to need.)

C. Stir to mix thoroughly
D. Do not touch the liquid silicone

V. Pouring

A. Begin pouring from one corner of flask, allowing silicone rubber to flow around the pattern
B. When pattern is half covered, stop pouring until RTV has leveled off
C. Resume pouring until pattern is covered at highest point with one-half inch of silicone rubber
D. Let it set up until firm
E. No extra safety precautions are necessary

VI. Stripping model

A. Remove RTV mold from flask
B. Remove pattern from mold
C. Remove flash, if any

VII. To cast replicas of original

A. Place mold in the flask for support
B. Make solution of paraffin wax and xylene as release agent, and apply it
C. Prepare silicone rubber as before
D. Pour, cure, and strip from mold as before

VIII. Application to Industrial Arts

A. Casting a mold of silicone is one of the industrial processes, using silicones, that we can perform in the school shop
B. The versatility of this material makes it particularly suitable for use in industrial arts

SUMMARY:

Silicone rubber molds are especially suited for the high temperatures of many casting materials. This material, because of its flexible properties, is filling great industrial needs where speed and economy is important.

QUESTIONS:

Q: What is the function of a catalyst in silicone RTV rubber?
Q: Silicone rubber molds will stay rigid up to what temperature?
Q: If a silicone original is cast, is it usable again? Why?
Q: If a release agent for silicones can't be bought commercially, what workable substitute is available?

FOR DISCUSSION:

. Factors influencing the choice of welds used in manufacturing
. Use of welding as a repair technique

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Have the student experiment with different welding processes.
. Fabricate a project by welding pieces of thermoplastic together.
. Develop a wall chart on different welding methods.

Eight basic weld types: *A) single-bead, single-V butt weld; B) multiple-bead, single-V butt weld; C) multiple-bead, double-V butt weld; D) corner weld; E) double fillet weld; F) and G) lap fillet welds; H) edge weld.* courtesy of Modern Plastics Encyclopedia

BRIEF DESCRIPTION OF PROCESS:

Cohesive bonding and adhesive bonding are two basic plastics joining processes. Cohesive bonding includes thermal welding and solvent cementing. Adhesive bonding involves the use of adhesive cements.

Thermal welding can be accomplished by use of: hot gas, high frequency, a heated tool, friction or ultrasonic waves.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Wall chart showing the basic methods of welding thermoplastics
. Samples of thermoplastic products that have been welded and cemented

LESSON OUTLINE:

I. Cohesive bonding. The molecular attraction by which the particles of two bodies are united and become one mass. Similar materials must be used for a cohesive bond. Two methods of achieving a cohesive bond are by thermowelding and solvent cementing.

A. Welding of Thermoplastics

- Hot gas welding. This is similar to gas welding of metal except that an open flame is not used (the high temperature oxidizing effects of an open flame will cause damage to plastic.) A stream of hot (425° F) compressed air or nitrogen gas is applied alternately to the material and a filler rod, causing them to melt. Moderate pressure is then applied to filler rod to complete the joint. This method is best suited to welding rigid sheets and pipes.
- Heated-tool welding. A heat source, such as a hot plate or heated knife, is used. The surfaces to be welded are melted or softened by the heated tool and butted together under pressure until the two edges bond to each other during the cooling period. This method is particularly applicable to welding of thin sheet or film.
- Friction welding (spin welding). This is done by rubbing mated parts together until the melting point is reached, at which point the rubbing is stopped. Pressure between the two parts is maintained until they have cooled, completing the bond. The rubbing action, which generates heat by friction, may be oscillating or rotational. Generally, the rotational method is the most convenient method. This type of welding may also be used to bond a thermoplastic to a thermoset plastic.
- High frequency welding (induction welding). High frequency waves or vibrations generated by a power source pass through electrodes that hold the thermoplastic materials together. These vibrations cause heat between the two plastic parts, and, when the correct temperature is reached, pressure is applied to complete the bond. This method is used for bonding thin sheets or films.
- Ultrasonic welding. This is achieved by pulsations from an ultrasonic generator which pass through the material to be welded. This hammering action generates heat, and the pressure from the holding device completes the bond.

B. Solvent cementing
- Solvent cements (ethylene dichloride, glacial acetic acid, etc.)
  a. Selected for specific plastic to be bonded
  b. Low-boiling solvents give fast setting action but may cause crazing in a short time
  c. Inexpensive method of cementing
- Dope cements
  a. Contain in solution a quantity of the same plastic which is being bonded
  b. Leave on drying, a film of plastic to aid in the bonding
  c. Are used for imperfect fits and where some filling is necessary
  d. Are easier to handle than regular solvent cements

II. Adhesive bonding. The adhering or sticking together of substances in contact with each other through the use of a sticky, glutinous substance.

A. The adhesive may be of a different chemical type than the plastic being bonded

B. Monomeric or polymerizable cements
- Consist of
  a. A reactive monomeric identical to, or compatible with, the plastic to be bonded
  b. A suitable system of catalyst and promoter
  c. Are polymerized at room temperature or at a temperature below the softening point of the plastics

C. Examples of adhesive bonding
- Bonding of thermosetting plastics with epoxy cements
- Plastic bonding cement used for model making

III. Techniques

A. Common joints used for bonding
- Lap joint
  a. Good appearance
  b. Good strength in many instances
- Butt joint
  a. Easiest type to provide for in molding
  b. Less contact area, weakening joint
  c. Unsightly bond lines
- Tongue-and-groove
  a. Self-positioning
  b. Amount of adhesive to be carefully controlled during application

B. Application methods
- Dip method
  a. One of the two parts dipped into the cement just enough so that the solvent will act on the desired area for maximum time
  b. Parts then assembled and held under light pressure for a short time
- Capillary method. Surfaces to be cemented are fitted closely, and cement is introduced into the edges of the joint and allowed to spread to the rest of the joint by capillary action

C. General technical considerations
- Clean surface on pieces to be bonded
- Proper contact of mating parts
- Care in application of adhesives to avoid disfiguration
- Enough clamping pressure on contacted surfaces where necessary

D. Industrial considerations: Basically, these methods can be used to bond plastics regardless of their shape; the intricacy of the shape and the material to be bonded will determine the method and the material to be used. Factors such as strength or appearance should be considered by the fabricator when deciding what method of cementing or welding should be used.

IV. Safety and hygiene

A. Work in a well ventilated room

B. Check volatility of material to be welded or cemented

C. Employ all general precautions used when working with hot plastics

V. Guidance - Jobs available

A. Welders

B. Layout men

C. Designers

D. Chemists

E. Engineers

VI. Science

A. Cohesive bonding - The molecular bond of the parent materials are loosened by heat or solvents. The two parent materials are put in contact with each other and when the solvent evaporates or the heat dissipates, the molecular bond is again strengthened causing the two parts to bond together.

B. Adhesive bonding - A sticky material which grips the parent materials when dried or cured, is placed between the two materials, holding them together by adhesion.

SUMMARY:

Welding thermoplastics has become an integral part of the plastics industry since 1940. Growth in size, technique, and understanding is still going on in this phase of the plastics industry. The future of welding and cementing plastics seems to be very good.

QUESTIONS:

Q: What are the five basic methods of welding plastics?
Q: Why can't an open flame be used for welding plastics?
Q: What is meant by spin welding?
Q: What are the industrial considerations for choosing a bonding method in plastics?
Q: What is the difference between adhesive and cohesive bonding?

Recommended methods of welding thermoplastics

UNIT IV BONDING

Lesson 20

Demonstration: Welding

OBJECTIVES:

- To demonstrate the various methods of thermoplastic welding
- To acquaint the student with the safety precautions to be taken in connection with the welding processes
- To develop an appreciation for fabrication of plastics by welding methods

REFERENCES:

1.	Cherry, Raymond	General Plastics Revised 1964	Chap. 16
2.	Kaminsky and Williams	Welding and Fabricating Thermoplastics Material, Kamweld Prod., Co. Norwood, Mass.	
3.	*Hain, George and Zade, H. P.	Welding of Plastics	
4.	*Newman & Brockhoff	Welding of Plastics	Ch. 2,5,6
5.	Simonds and Church	Concise Guide to Plastics	pp. 183-6
6.	SPI	Plastic Engineering Handbook	pp. 501-7
7.	Swanson, Robert	Plastics Technology	pp. 214-15

FOR DISCUSSION:

- The five basic methods of thermoplastic welding
- The proper selection of a welding method for the job to be done
- The historical development of the plastic welding processes

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

- Practice welding samples of different types of thermoplastic materials.
- Discover and identify welds on commercial plastics products.
- Have the student fabricate a project using welding as a process.

BRIEF DESCRIPTION OF PROCESS:

Welding is a process of joining two or more items of the same material under the influence of heat and pressure. There is no problem of solvent evaporation or curing time as in the use of adhesives. A welded item may be handled in a reasonable amount of time. Time and money may be saved in the fabrication of thermoplastic products using these methods.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

- Wall chart depicting various processes of welding and general procedure for each (Modern Plastic Encyclopedia 1962, pp. 844-845)
- Thermoplastic rod and sheet of identical material (Kamweld Corp.)
- Heat source for heated tool method (Hot plate, heat-sealing tool, soldering iron)
- Drill press
- Available welding equipment for thermoplastics (Hot gas welder, plastics flow gun, electric soldering iron)

LESSON OUTLINE:

I. Hot gas welding

A. Secure objects to be welded so they will not move during welding operation. (Pin, tack, or tape to a solid surface.)

B. Check the heating element to be sure it is the proper one for temperature that will be needed. (Temperature needed varies with the material to be welded. See manufacturer's specs.)

C. Close the regulator before connecting the air or gas supply. After connecting the air or gas, adjust regulator for proper pressure (approx. 2-6 pounds on the gauge). Lowering the pressure will increase the heat.

Typical set-up *for hot-gas welding of thermoplastics materials, using an electrically heated gun. Welding rod used (far left) is of the same composition as the parts which are to be welded together*

courtesy of Modern Plastics Encyclopedia

D. Connect to electric outlet

E. Allow about 3-4 minutes for warm up. The gas or air should flow through the barrel at all times to prevent the burning-out of the heating elements during preheat and welding.

F. Select the tip needed for the job to be done. Install by holding the tip with pliers to prevent burning of fingers or hands.

G. Select the filler rod (should be of same material as items to be welded; large diameter for thicker sheets, etc.)

H. Brush the stream of hot air or gas between the filler rod and material to be welded. When both the rod and the material become tacky, begin the welding process.

I. Hold the filler rod to material and feed the rod progressively as it and the material become tacky. Hot air stream should be directed so that 40 percent of it hits the filler rod and 60 percent hits the material to be welded. Continually move the air stream to produce an even weld.

J. When the weld is complete, filler rod may be twisted off while it is still soft

II. Heated-tool welding

A. Place joint edges on a heat source and hold until both edges reach the proper temperature. The temperature will vary with the type of material to be used. Use mold release on heat source to prevent sticking.

B. As soon as the materials are properly heat softened, remove them from the heat source and join them together quickly

C. Hold them together firmly until the melted material cools to form a strong joint

III. Friction welding

A. Mount a piece of round plastic filler rod stock in the drill press

B. Secure a piece of sheet of the same material as the filler rod to the drill press table

C. Start the drill and feed it down until the rod comes into contact with the sheet

D. Hold down with approximately 20 lbs. of pressure until contact points become heat softened

E. Stop the drill quickly and maintain pressure until the material cools to complete the bond

Spin welding *of locking button to knob of automobile window crank is accomplished with a special tool. (From a Du Pont sketch)*

courtesy of Modern Plastics Encyclopedia

IV. Ultrasonic and high frequency welding. Refer to section on heat sealing (Lesson 21).

V. Safety

A. Never handle hot gas tips by hand
B. Never direct hot gas flow toward other people
C. Do not handle hot plastics without gloves
D. Check volatility of material to be welded
E. Work in a well ventilated room

SUMMARY:

Welding is the process of bonding two items of the same material under the influence of heat and pressure. Welding is being used more and more every day as an industrial fabrication process. It is fast, easy, and comparatively inexpensive. This makes it a practical industrial fabrication method.

QUESTIONS:

Q: Describe hot gas welding of thermoplastics.
Q: Should the heat source for the heated-tool method be coated with a lubricant or mold release?
Q: What types of motion can be used in friction welding?
Q: List 5 safety rules for thermoplastic welding.
Q: What is meant by volatility?

UNIT IV BONDING

Lesson 21

Related Lesson: Heat sealing

OBJECTIVES:

. To introduce the student to the heat sealing process.

. To point out the industrial uses of heat sealing.

4.	Simonds and Church	Concise Guide to Plastics	pp. 102-103

FOR DISCUSSION:

. Products in which industry employs the heat sealing process
. Scientific principles of heat sealing
. Equipment used by industry
. Materials which are heat sealable

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Heat seal a card holder for a wallet.
. Incorporate heat sealing in a class production problem.
. Make a simple heat sealer.

BRIEF DESCRIPTION OF PROCESS:

Heat sealing refers to the welding of thin, thermoplastic sheetings or films to the same type of plastic, or to other materials, by heating.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Chart of materials and temperatures for heat sealing plastics (see Ref. #2)
. Examples of heat sealed articles
  - Roll bags
  - Plastic baby pants
  - Plastic raincoat
  - Meat packages

LESSON OUTLINE:

I. Historical development

  A. Heat sealing has been used for many years
  B. Used extensively in packaging, clothing, upholstery
  C. New methods developed to do special jobs

HEAT-SEALING TEMPERATURE RANGES FOR PLASTIC FILMS

Film Type	Range (°F)
cellophane (coated)	200-350
cellulose acetate	400-500
CFE (chlorotrifluoroethylene)	415-450
polyester (coated)	490
polyethylene	250-375
polystyrene (oriented)	220-300
polyvinyl alcohol	300-400
polyvinyl chloride and copolymers nonrigid	200-400
polyvinyl chloride and copolymers, rigid	260-400
polyvinyl chloride nitrile rubber blend	220-350
polyvinylidine chloride	285
rubber hydrochloride	225-350
FEP (fluorinated ethylene-propylene copolymer)	600-750
TFE (tetrafluoroethylene polymer)	cannot be welded
CFE (chlorotrifluoroethylene polymer)	satisfactorily

151

II. Methods of heat sealing

A. Electrical resistance sealing
- Jaws, rollers, metal plates or bands heated by electricity are in contact with materials to be sealed
- Material is touched by these heated jaws thus welding material together
- The following are the major materials which may be sealed:
  a. Cellulose acetate, cellulose butyrate (not sealable - cellulose nitrate and cellophane)
  b. Vinyls - saran for food packaging
  c. Polyethylene - dry cleaning bags; roll bags
  d. Polystyrene - card cases
  e. Materials which have been coated with heat sealable plastics

B. High frequency generation (Frequency near that of radio)
- Uses electrical properties of material (dielectric)
- Develops heat within film
- Vinyls such as those employed in the fabrication of raincoats and plastic boots seal best with this method
- Has limited use aside from vinyl

C. Ultrasonic generation (20 to 40 K.C.)
- Mechanical vibrations in sealing area develop heat losses which melt plastic surfaces causing seal
- Will seal through contaminates
  a. Printing on plastics
  b. Material contained in the package (frosting, etc.)
- Seals most plastic materials

D. Heat shrinking
- Plastic sealed around article being packaged
- Package heated with hot water or hot air
- Plastic shrinks and eliminates some of the air present
- Makes an attractive looking package

SUMMARY:

Heat sealing is used to advantage in many industries. It can be used to speed packaging operations and make the package more attractive. Heat sealing can give these articles waterproof seams that are as strong as the material itself.

QUESTIONS:

Q: Name some products heat sealed by the electrical resistance method.
Q: Heat sealing usually refers to the welding of what thicknesses of plastics?
Q: Is nitro cellulose a heat sealable plastic?
Q: What type or classification of plastic may be heat sealed? (thermoplastic or thermosetting?)
Q: Explain the theory by which the ultrasonic sealer works.
Q: Name some materials which can be sealed by high frequency generation.

15121

UNIT IV BONDING

Lesson 22

Demonstration: Heat sealing

OBJECTIVES:

. To show how heat sealing may be accomplished

. To demonstrate heat sealing as it is used by industry

REFERENCES:

1.	Redfarn and Bedford	Experimental Plastics	pp. 89-90
2.	SPI	Plastics Engineering Handbook	p. 501
3.	Simonds and Church	Concise Guide to Plastics	pp. 102-103

FOR DISCUSSSION:

. The temperatures involved in heat sealing
. Uses of heat sealing equipment
. Types of industrial heat sealing equipment

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Experiment with heat sealing on various plastic films.
. Make a kite using plastic film which can be heat sealed.
. Experiment with most common heat sealable plastics.

	Heat seal temperature
- Vinyl	200° to 400°
- Coated cellophane	200° to 350°
- Polyethylene	250° to 375°
- Cellulose acetate	400° to 500°
- Polystyrene	220° to 300°

See chart Related Lesson: Heat Sealing; also Ref. #3 above

BRIEF DESCRIPTION OF PROCESS:

Thermoplastic sheet (material thicker than 10 mils (.010) in thickness) or film (material thinner than 10 mils) may be bonded together by applying heat and pressure to a narrow strip of the materials so that they fuse or weld together.

MATERIALS, EQUIPMENT, AND/OR TEACHING AIDS:

. Clothes iron, with temperature control
. Electric soldering gun or wood burning pen
. Variable transformer
. Commercial heat sealer
. Two-sheet metal strips 20 ga. x 1/8" x 10"
. Vinyl film
. Cellophane, coated
. Polyethylene
. Cellulose acetate
. Temperature chart
. Silicon spray (mold release)
. Newspapers
. Hair dryer
. 10" x 10" plastic sheet from meat market
. Small spring clamps

LESSON OUTLINE:

I. Heat sealing using clothes iron

A. Set temperature control to temperature required. (See heat chart.)
CAUTION: Do not touch the hot iron
B. Spray iron and sheet metal strips with silicon spray
C. Clamp double thickness of plastic between metal strips
D. Place iron on top strip until plastic softens slightly
E. Remove iron; unclamp; let cool

II. Using soldering gun or wood burning pen

A. Spray tip with silicon release
B. Turn on variable transformer
C. Check heat tip with thermometer to get correct heating temperature
CAUTION: Do not touch the tip
D. Place double thickness of plastic on stack of newspapers
E. Draw tip in straight line over surface of plastic
F. Let cool

III. Using commercial heat sealer (has rollers, strips, or clamps which come in contact with plastic. CAUTION: Do not touch the heated edges)

A. Preheat sealer to proper temperature
B. Heated strip is usually coated with nonstick material
C. Clamp plastic between jaws
D. Hold for approx. 30 seconds
E. Unclamp and allow to cool

IV. Heat shrinking plastic packages, using clothes iron and portable hair dryer

A. Use plastic from meat market (approx. 10" x 10" of film one side of which is coated with a sweet tasting coating which keeps food from spoiling)
B. Wrap plastic around crumpled newspaper, placing "sweet side" against paper
C. Heat seal on sole of clothes iron
D. Hold hair dryer approximately 10 inches from package
E. Heat surface until plastic shrinks and tightens around newspaper

SUMMARY:

Heat sealing is used to make many items from plastic film. It forms strong, waterproof joints or welds on the material sealed. Heat sealing is used extensively in packaging to make attractive, practical packages.

QUESTIONS:

Q: How does heat affect plastic in heat sealing?
Q: Why do we use pressure in heat sealing?
Q: Name some heat sealable plastics.
Q: Name three methods of heating sheets and films for heat sealing.

6. *Whitney Publishing Company	Industrial Design 18 E. 50th Street New York 22, N. Y.	Oct. '58

FOR DISCUSSION:

- Computing costs of glass fiber for hand layup
- Fillers and their purpose
- Mold designs for reinforced plastics
- Uses and types of plastic automobile body solders

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

- Make a model boat, car body, tray, etc., using the open mold process.
- Make a project utilizing the pressure bag method.
- Make a project utilizing male and female matched molds.
- Take a field trip to industry employing hand layup method of reinforced plastics.
- Experiment with various reinforcing materials.
- Mix a polyester resin and use in hand layup (Ref. #3).

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

- Flip chart, pictures, etc. of basic reinforcing methods
- Large photos or drawing of glass fiber to include cloth, mat, roving, chopped strands, fibers, and others
- Samples of reinforcing materials

BRIEF DESCRIPTION OF PROCESS:

By the addition of reinforcing materials such as glass fibers, asbestos, or sisal the shock resistance and strength of the plastic binder can be greatly increased.

Commercially large items are possible using dies or molds to shape the plastic. Boat hulls and large tanks are commonly made of reinforced plastics.

Hand layup is accomplished by applying a reinforcing material and a polyester resin in, on, or around a mold. The process is similar to pouring concrete around reinforcing steel except that plastic is used as the binder instead of concrete. The plastic requires special treatment for gelling, curing and specific pre coating and post coating operations.

The hand layup method affords definite advantages for the school shop since it utilizes a low cost polyester resin which will cure at the normal atmospheric conditions of the classroom.

LESSON OUTLINE:

I. History of reinforced plastics

A. World War II application
- Resin developed by early 1900's
- Glass fiber developed by Corning in late 1930's
- In 1940's great industrial stimulus provided by World War II needs such as
  a. Bullet resistant outershells for airplane gas tanks, bullet proof vests, landing boats, etc.
  b. Coating to prevent bullets shattering tank's inside liner

B. Post World War II use
- War applications cease; use of materials very limited
- Late 1940's, reinforcements are revived with great growth in numerous areas; little commercial coordination
- In 1950's, large growth of market application. (NOTE: see SPI Press Release 1964 for current history - See also current issues of Modern Plastics magazine)

II. Advantages of fiber glass reinforced plastics

A. Superior strength
- Impact
- Flexural
- Tensile
- Compression

B. Protective characteristics
- Electric arc resistance
- Chemical resistance

C. Versatility of application
- Low cost per item
- Fabrication of large items
- Simple moldmaking in comparison to injection or compression molding
- Simple hand tools needed
  a. Paint brushes, rollers, squeeges
  b. Parting agents, such as, carnauba wax or silicone

III. Materials

A. Polyester Resin
- What it is
- How it is made
- Theory of cure
  a. Mixture of components
  b. Resin activitated by exothermic heat to align molecules
  c. Long chain of molecules form gel state
  d. Cross linking occurs, solid state
  e. Resin locks around reinforcing material
- Thinning agents - styrene monomer
- Catalyst - MEK peroxide and others
- Color pigments - in suitable carrier
- Solvents - resin-out and acetone

B. Other Resins
- Epoxy
- Silicone
- Phenolic
- Melamine
- Thermoplastic

C. Types of reinforcements
- Glass fiber made from glass, processed into several forms
  a. Cloth
  b. Mat
  c. Roving
  d. Fiber
  e. Chopped strands
  f. Chips and/or ground fiber
- Minor types of reinforcements used
  a. Cardboard
  b. Asbestos
  c. Silica
  d. Others

IV. Sample products for school shop program

A. Flat tray-method, open mold
B. Dish-method, male and female mold
C. Boat hull-method, open or pressure bag mold
D. Others

V. Occupational-industrial potentials

A. Job shop
B. On the job repair and maintenance
C. Manufacturing of large items and small quantity production
D. Other areas where uniformity is not critical

SUMMARY:

Hand layup of polyester resin and reinforcements have the chief advantage of being applicable to short production runs where a strong article is desired. A minimum of equipment is necessary, and molds are relatively inexpensive. This material is easy to use in the shop because most of the work can be done with hand tools. The polyester resin, when combined with a reinforcement, provides a durable, lightweight, high strength product.

QUESTIONS:

Q: Describe the advantage of hand layup of polyester reinforced plastics in the small shop.

Q: Describe the types of glass fiber materials used in glass reinforcements.

Q: What chemical reaction takes place when MEK peroxide is mixed in polyester resin? Describe by drawing the four simplified diagrams of molecular states.

159

UNIT V LAMINATES

Lesson 24

Demonstration: Reinforced plastics

OBJECTIVES:

. To show the procedure for a hand layup of polyester reinforced plastic

. To acquaint students with some techniques and visual checks in hand layup of polyester reinforced plastics

REFERENCES:

1.	Bick, Alexander F.	Plastics: Projects and Procedures with Polyesters	pp. 1-64
2.	Cope Plastics Hwy #100 Godfrey, Ill.	"How to Make Useful and Decorative Bowls with Fiberglass Cloth - Polyester Resin"	Information sheet
3.	*Sonneborn	Fiberglass Reinforced Plastics	General
4.	Steele, Gerald	Fiber Glass - Projects and Procedures	All

FOR DISCUSSION:

. The four stages of polyester resin
. Types of molds and how they are used
. Types of mold releases used
. Safety, room ventilation, eye protection, skin protection, necessary when using resins and catalysts

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Do a layup of an open mold (model boat hull, dish, etc.).
. Design, build mold and make project from original mold.
. Do a layup project using male and female mold, (dish, cup, etc.).
. Experiment with reinforcements other than glass fiber.

BRIEF DESCRIPTION OF PROCESS:

The hand layup procedure follow four general steps: (1.) preparation; (2.) mixing of gel coats and/or resin with catalyst; (3.) layup or application; and (4.) product finishing. (The process is written in general terms and should be supplemented with a specific reference to manufacturer's instructions. Specific reference is made to visual checks for students.)

MATERIALS, EQUIPMENT, AND/OR TEACHING AIDS:

. Polyester resin and catalyst
. Gel coat resin and catalyst
. Mold(s)
. Mold release
. Brush, roller, tin cans for washing, paper cups
. Acetone or lacquer thinner
. Shop apron, rags, disposable gloves
. Bench covering - newspaper, cardboard
. Reinforcement - fiber glass, mat, cloth, roving, etc.
. Scissors, knife

. Stirring sticks
. Fine sandpaper

LESSON OUTLINE:

I. Preparation

A. Materials and tools
- Cut reinforcement to mold shape allowing for slight waste
- Assemble resins, catalysts, acetone, mold releases, tools, etc., on bench
- Use small mouth can as container for acetone for easy rinsing of tools after resin application
- Wear shop apron and disposable polyethylene gloves
- Provide adequate air circulation (adequate size exhaust fan)
- Maintain room temperature at about 70-75 degrees F
- Lay cardboard on bench top

B. Mold(s)
- Clean mold surfaces using rag
- Apply mold release carefully to all surfaces; follow manufacturer's instructions. Use two coats.

II. Mixing of resin

A. Gel coat (if used). Follow instructions for proportions.
- Pour out desired amount in clean cup or can (approx. 1 oz. per square foot of surface)
- Add catalyst and stir thoroughly (usual percentage of catalyst is 1% to 2%; 4 to 8 drops per oz. of resin
- Brush or roll resin on to mold surfaces
- Clean tools with acetone rinse
- Allow to cure; sand surface thoroughly to remove any surface wax from cured gel coat

B. Polyester resin. Follow manufacturers instructions for proportions of resin and catalyst.
- Pour resin needed into clean cup or can
- Add catalyst (1% or 4 drops per oz.) and stir thoroughly; look for change in color from pink to amber. Resin is now in catalyzed stage and must be used within a short time.

III. Layup or resin reinforcement process

A. Apply resin with brush or roller; resin should coat all surfaces to be covered

B. Lay on reinforcement

C. Apply polyester resin and saturate reinforcement, bearing in mind the following techniques:
- Saturate all reinforcement in mold
- Use stipple effect of brush to work out air bubbles
- Keep reinforcement in place and use small scraps if extra strength is needed
- Apply more resin to high areas of mold. (Resin has tendency to run to low portion of mold.)
- Take care to avoid uneven saturation, resulting in resin rich areas and resin starved areas
- Assemble and put pressure on male mold (if used)

D. Rinse brush or roller in acetone

E. Clean area, including hands. (Wash hands with soap and water.)

F. Allow for complete curing of resin. Notice milky substance as resin gels; further gelling aligns molecular structure into 3-dimensional cross-linking, which is the cured stage of resin.

IV. Product Finishing

A. Parting from mold
- Check for and trim any hardened waste on edges
- Lift off evenly. (Slight prying may be needed.)

B. Cleaning up mold

C. Finishing product
- Trim edges with saw, sander, plane, etc.
- Remove release agent by wiping
- Proceed with assembly of product as necessary

SUMMARY:

The hand layup of polyester reinforced plastic is an excellent method for the making of limited or low production items. The reinforcement is thoroughly saturated with catalyzed resin, and the gelling-to-curing cycle is readily visable. Safety considerations in the use of the polyester resin are; ventilation, body protection, and equipment protection. The finished product is strong and has the advantages of low cost and high durability.

QUESTIONS:

Q: What are the four steps in the polyester resin molecular cycle?
Q: What are the four general areas of procedure in the hand layup method of reinforcing polyester resin?
Q: Describe the difference between a resin rich and a resin starved area as applicable to working with polyester reinforcements.
Q: What are the major safety factors involved in the use of polyester reinforcements during the hand layup procedure?

UNIT V LAMINATES

Lesson 25

Related Lesson: Low pressure lamination

OBJECTIVES:

To develop an understanding of the process of low pressure heat lamination

REFERENCES:

1.	Cherry, Raymond	General Plastics, 1964 Rev.	Chap. 20
2.	Duffin, D. J.	Laminated Plastics	
3.	Edwards, Lauton	Industrial Arts Plastics	Chap. 18
4.	Simonds and Church	A Concise Guide to Plastics	pp. 172-173
5.	SPI	Plastic Engineering Hand Book	pp. 495
6.	Warner Electric	(Company literature on laminating press)	Warner Electric Co. 1512 Jarvis Ave. Chicago 26, Ill.

FOR DISCUSSION:

. The use of lamination in all areas of plastics
. The types of laminate materials available and their intended uses

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Heat seal a photograph between sheets of acrylic plastic.
. Make a project with embedded articles, i.e., cuff links, broaches, etc.
. Experiment with different types of sheet plastic stock at varied temperatures and pressures.
. Laminate a social security card or other cards (after satisfactory results with practice cards).
. Laminate plastic to other materials (cloth, paper, leather).

BRIEF DESCRIPTION OF PROCESS:

Lamination is the process used to form a bonded product made up of several layers of plastic and other materials. Heat and pressure are used to bond the sandwich-like layers together.

Low pressure lamination is generally accepted as bonding accomplished below a pressure of 300 psi. Plastic sheets usually form the surface over objects such as cards, photos, and similar items.

MATERIALS, EQUIPMENT, AND/OR TEACHING AIDS:

. Samples of low pressure heat lamination
. Samples of pressure sensitive lamination
. Diagram of the lamination process

LESSON OUTLINE:

I. Heat Lamination

A. Purpose
- To seal for protection (identification cards, etc.)
  a. Moisture
  b. Damage
- To beautify and decorate (cuff links, etc.)
  a. Embedding small items
  b. Vari-colored effects

B. Materials
- Low cost
  a. Acetate
  b. Butyrate
- High cost
  a. Acrylic
  b. Vinyl

C. Technical considerations
- Not larger than press platens
- Edge overlap to form seal, 1/8"
- Item embedded able to withstand 400° F

II. Pressure sensitive lamination

A. Purpose. To seal for protection
B. Materials. Plastic sheet with pressure sensitive adhesive on one side
C. Procedure. To be applied to the surface of the item to be protected after removing backing paper, pressing evenly

III. Industrial applications

A. Local job shops - diplomas, cards, photos, etc.
B. Specialty manufacturing
C. Industrial - identification cards, etc.

SUMMARY:

Low pressure heat lamination utilizing acetate, butyrate, acrylic, and vinyl sheet plastics is a simple process and serves a practical purpose in finished products. The items laminated are placed between two or more sheets of plastic and heated under pressure to seal or fuse the contacting sheet plastic around them. Pressure sensitive laminations may also be made. Occupational opportunities appear limited to job shop and similar situations.

QUESTIONS:

Q: Why are identification cards laminated with sheet plastic materials?
Q: Of what value, industrially, is low pressure heat lamination? Why?
Q: Describe the basic process of low pressure heat lamination.
Q: Describe pressure sensitive lamination.

C364

UNIT V LAMINATES

Lesson 26

Demonstration: Low pressure laminating

OBJECTIVES:

. To demonstrate the procedure for low pressure laminating

. To laminate an item with sheet plastic

REFERENCES:

1. Cherry, Raymond	General Plastics 4th. Ed. 1964	Chap. 20
2. *Duffin, E. J.	Laminated Plastics	General Info
3. Edwards, Lauton	Industrial Arts Plastics	Chap. 18

FOR DISCUSSION:

. Laminating temperatures of different thermoplastic sheet materials in relationship to each other

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Laminate plastic sheet over general organization card or student membership card.
. Test various plastics for laminating qualities.
. Develop a chart to give best heating ranges for different kinds of plastic in sheet form, thicknesses of sheet, and items to be laminated.
. Develop thicker laminations (over fishing flies, etc.).

BRIEF DESCRIPTION OF PROCESS:

The item to be laminated is sandwiched between two sheets of plastic stock and the sandwich is heated to a controlled temperature. Overlapping plastic sheets form around the item, creating an encased thickness slightly more than the original thickness of the items before lamination? Items are put under pressure, cooled under pressure, and trimmed. Pressure sensitive laminates may also be used for protecting items.

MATERIALS, EQUIPMENT, AND/OR TEACHING AIDS:

. Thermoplastic sheet stock (acrylic, acetate, vinyl and others)
. Item to be laminated (social security card, fishing license, etc.)
. Laminating press to include two (2) slick facing sheets. (Capacity of press approx. 300 psi with 310° - 350° heat range)
. Carnauba wax to coat facing plates
. Scissors, tin snips, or other sheet cutting tools
. Fine sandpaper
. Water supply and drainage for cooling press

LESSON OUTLINE:

I. Selecting and cutting the sheet stock

A. Choose stock from one of the following stocks suitable for low pressure laminating
- Acrylics
- Acetates
- Vinyls (unplanished)

- Others (See manufacturers specs. for details on heat, pressure, and time cycles.)

B. Determine size
- Size and capacity of press (item not to exceed platen size)
- Size of item to be laminated, including thickness of item
- Overlap on items (rough 1/4" minimum overlap to get 1/8" minimum finished overlap)

C. Cut to measured size with snips, squaring shear, etc.

II. Preparation and press preheating

A. Preheat the press to desired temperature. (Check manufacturer's specifications of heat required for plastic stock being used.)

B. Clean and wax facing plates as necessary

C. Dry run the complete sandwich into the press opening to check for fit

D. Dry item to be laminated. Trapped moisture causes fogginess in the laminate

III. Operating procedure for laminating

A. Set up sandwich (in sequence)
- Back up plate
- Heat distribution or cushion sheets, blotters, etc.
- Slick facing sheets (chrome plated sheets and/or ferrotype plates)
- First plastic sheet
- Item to be laminated
- Second plastic sheet
- Slick facing sheet
- Heat distribution or cushion sheets
- Back up plate
- The above 9 items clamped together by the plates with vice grip, wrench, or "C" clamps

B. Heating cycle
- Insert clamped sandwich (1-9, above) in heated press and apply pressure, (Formula: total load lbs = psi required x sq. in. of surface area)
- For each laminated item in stack, add proportionate time to heating cycle, but do not add more pressure
- Release the pressure and remove the clamped stack
- Place stack in cooled portion of the press and apply same pressure for same time as for heating cycle
- Remove the cooled stack and unclamp the vise grips
- Label the press and hot items as "HOT"

IV. Trimming laminated items

A. Trim all edges to a minimum of 1/8" overlap all around

B. Sand or polish the sharp edges of the laminate

SUMMARY:

Low pressure laminating of sheet stock depends on the proper application of heat and pressure. The time cycle for heat fusing and cooling is equal. Pressure is maintained throughout the heating and cooling cycles.

The item laminated has a sealed edge around it and also has its surface covered with the plastic stock. The protective qualities conferred by this type of lamination are excellent for items handled repeatedly.

QUESTIONS:

Q: What are the requirements for a successful low pressure heat laminate?
Q: What condition causes fogginess under laminated sheet?
Q: How can fogginess be eliminated in low pressure heat lamination?

UNIT V LAMINATES

Lesson 27

Related Lesson: High pressure laminating

OBJECTIVES:

. To develop in the student an understanding of high pressure laminates

. To acquaint the student with the uses of this material

REFERENCES:

4. Hutchings and Lindbeck	Panelyte in the School Shop	pp. 1-6
5. Simonds and Church	Concise Guide to Plastics 2nd Edition	pp. 170-173
6. Redfarn and Bedord	Experimental Plastics	p. 73

FOR DISCUSSION:

. Types of laminates
  - Resins and fibrous materials used
. Coating or wetting process employed

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Make a list of the places where high pressure laminates are used in the home.
. Compare plastic laminated countertops and finished wood countertops.
. Make some high pressure circuit boards.

BRIEF DESCRIPTION OF PROCESS:

High pressure laminates are multilayer sandwich structures. They consist of sheets of various materials bonded with adhesive resins. After bonding they are molded and cured at pressures not lower than 1000 psi. Pressures of 1200 psi are commonly used. Formica and Micarta are common trade names.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Chart #1 showing laminate structure of solid sandwich
. Chart #2 showing preparation of fibrous sheets
. Formica counter top material of sandwich construction
. Printed circuit board of solid construction

High Pressure Laminate Construction
courtesy of Panelyte Division, St. Regis

LESSON OUTLINE: (Ref. #5)

I. Development of high pressure laminates

A. Production low before World War I
B. Vulcanized fabric (rubber base) produced by Continental-Diamond in 1911
C. Resins for laminating became available in the 1930's
D. Phenolics first used for laminating resin

II. Structural types of high pressure laminates (Ref. #3)

A. Solid Construction. Multiple layers of fibrous sheets and resin binder are compacted into a homogeneous unit. Facing sheets may be of two different materials.
B. Sandwich construction. A construction involving the bonding together of a relatively thick, low density core and thin, high strength facing sheets.

III. The Fibrous materials used (Ref. #2)

A. Papers - Kraft, Alpha, Rag (cotton fibers)
- Quality desired in end product is the determining factor in choice of fiber material to be used
- Construction employed often uses core stock with decorative sheets overlayed
- Large quantities used for production of printed circuitry

B. Cotton cloth
- Various weights and weaves used in wide range of applications
- High strength obtainable through use of heavy fiber
- High impact strength possible for use in gears and pulleys

C. Glass cloth
- Becoming very popular
- High strength, chemically resistant
- Difficulty in wetting or soaking this cloth with resin

D. Asbestos felts, mats, papers
- Felts are 10 mils or under in thickness; Mats are over 10 mils
- May be purchased with or without resin binder
- Used with phenolic resin for high heat resistance

IV. Resins (Ref. #2)

A. Phenolic resin most common. 105 million pounds used for laminating in 1963
- Good adhesion
- Limited color selection
- Made in 16 different electrical grades
- Heat resistant up to 300-350° when combined with epoxy

B. Melamines. 32 million pounds used for laminating in 1963
- Wide color range
- Abrasive and acid resistant
- Used for table tops, counters

C. Polyesters
- Short cure time
- Ease in coloring
- Ease in dissolving for wetting process

D. Other resins
- Acrylics, fluorocarbons, epoxies, etc.

V. Preparation and function of materials and equipment (Ref. #4)

A. Resins
- Powder or pellets dissolved in solvent (ketones, alcohol, etc.)
- Also available in prepared liquid form

B. Coating process or wetting process (Use chart No. 1)
- Machine - coating and drying
- Wetting - coating material with resin
- Drying chamber - removes volatiles from resin
- Re-coating sometimes necessary

C. Patterned sheets-used in sandwich construction laminates
- Paper with high wet strength
- Printed if desired, coated with resin
- Transparent overlay - need a high percentage of resin

D. Facing sheets for solid construction laminates
- Copper, steel, aluminum alloys, cork and vulcanized fiber
- Sheets are treated on surfaces as needed for adhesion
- Films of polyester and cellulose acetate also used

VI. Laminating presses

A. Sheet stock press (Ref. #2)
- Vertical action with single or multiple platens
- Platens plated or highly polished
- Separate plates of stainless or chrome
- Very large platen sizes up to 80" long, 40" wide
- Platens heated with steam, electricity or water (under pressure)

B. Molding presses
- Shaped dies may be used in place of flat plates
- Used for intricate forms

C. Tube winders. Used to make tubes and rods

VII. Application of high pressure laminates (Ref. #1)

A. Automotive - timing gear
B. Electrical - printed circuits, switchboard panels
C. Home use - countertops and table tops

SUMMARY:

With the use of different combinations of fillers and resins, a wide range of high pressure laminates may be produced. The different combination will give the laminates different mechanical, electrical and chemical properties, tailor made for specific applications.

QUESTIONS:

Q: What is meant by high pressure laminating?
Q: What is the difference in solid and sandwich construction of high pressure laminates?
Q: What are some common fibrous materials used in high pressure laminating?

UNIT V LAMINATES

Lesson 28

Demonstration: High pressure laminating

OBJECTIVES:

. To give the students an understanding of how high pressure laminates are made

. To show the students some of the common materials used in this process

REFERENCES:

1. *Duffen, D. J.	Laminated Plastic	Chaps. 4-5

FOR DISCUSSION:

. Factors determining choice of laminating resins
. Factors determining choice of laminating filler materials

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Projects: drum practice pad, printed circuit plates.
. Experiment by laminating different materials at different heats, pressures and times.
. Experiment by compounding different resins and fillers for making core stock.

High Pressure Laminating
courtesy of The Society of the Plastics Industry

BRIEF DESCRIPTION OF PROCESS:

High pressure laminates are multilayer sandwich structures with sheets of the same, or various stocks, bonded with adhesive resins, molded and cured at pressures not lower than 1000 psi and more commonly in the 1200 psi range.

Formica, Panelyte, Micarta, Synthane, and Dilecto are some of the common trade names.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Laminating Press
. Polished Plates
. Materials - impregnated material available
. Pressure pads, kraft paper, blotter material
. Asbestos gloves
. Drawing or photograph of plastics laminating press

LESSON OUTLINE:

I. Machine description

A. Platens
- Heat source. Electricity, steam, or hot water
- Size. Laboratory models, 6" x 6" to about 10" x 12". Up to 40" x 80" in industry
- Ram connected at botton (force or chase)
- Adjustable - change daylight between platens

B. Columns
- Alignment - keeps platens parallel
- Allow for travel of platens

C. Press mechanism. On laboratory models, 10 to 30 tons; up to 200 tons and more on industrial types)
- Hydraulic jack
- Pressure measured in load pounds for vertical movement

II. Auxiliary equipment

A. Facing plates (placed next to material to give a good surface texture)
- Stainless steel or chrome plated
- Finishes vary
  a. High gloss
  b. Dull matt
  c. Embossed - special jobs

B. Pressure pads
- Unsaturated kraft paper or ink blotter material
- Purposes
  a. Cushions to minimize temperature and pressure differences
  b. Shields to protect plates, reduce wear

III. Materials used in process

A. Kraft paper impregnated with phenolic resins
B. Resins: polyester, melamine
C. Fibrous materials: cotton, asbestos, glass and fiber cloth

IV. Laminating process

A. Preheat pressure plates to 250° - 300°

B. Cut core and facing sheets to size for sandwich construction

C. Place facing sheet in place on top of sandwich

D. Apply mold release to plates

E. Place plates on top and bottom of materials

F. Position pressure pads on outside surface of top and bottom plates

G. Place pack between heated plates (285° - 300°)

H. Apply calculated pressure to plates
- Commonly about 1000 psi, occasionally up to 2000
- Pressure figured by load in pounds - no. square inch x psi recommended for material
- Allow continuous pressure for from 20 min. to 12 hours (depending on material used, as recommended by manufacturer)

I. Remove pack and disassemble

V. Safety

A. Wear gloves when handling hot plates and when working around heated press

B. Label hot materials and press

SUMMARY:

Good results from high pressure lamination depend on the use of proper temperatures, pressures, and curing time for materials being used. Careful control of these variables govern the quality of material produced.

QUESTIONS:

Q: What function do the polished plates serve in high pressure lamination?

Q: What purpose do the pressure pads serve in high pressure lamination?

Q: How would you figure load pounds for a given material to be used in high pressure laminating?

UNIT VI

ENCAPSULATION

Lesson Page

29 Casting and embedding (demonstration) 104

174

UNIT VI ENCAPSULATION

Lesson 29

Demonstration: Casting and embedding

OBJECTIVES:

. To teach the student to case and embed materials in plastic resins

. To teach students to work with thermosetting plastic resins

REFERENCES:

1. Bick, Alexander F. — Plastics: Projects and Procedures with Polyesters
2. Castalite Co. — How to use Castalite
3. Holt, Elmer — Casting in Clear Plastic
4. *Harden, Cleo E. — How to preserve animal and Other Specimens in clear plastic
5. *Pearson, Hazel — Liquid Plastic Artistry
6. SPI — Plastics Engineering Handbooks

FOR DISCUSSION:

. Protection of electronic components by potting as protection from vibration and atmosphere
. Casting as an economical method of preserving biological specimens
. Theory of cure in polyester and other thermosetting resins
. Methods of determining specific gravity

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Select and embed a coin, stone or biology specimen.
. Arrange and embed shells and similar materials to form an artistic or decorative scene or form.
. Experiment with different resins, catalysts, and cure cycles to determine one with the least possible shrinkage.
. Demonstrate the cracking or crazing caused by rapid cure cycles.
. Measure the heat of cure for various cure cycles and conditions.

BRIEF DESCRIPTION OF PROCESS:

Embedding, often referred to as casting, potting, and/or encapsulation, is a process where by an object such as a coin, biological specimen, or electrical component is placed in a liquid plastic material and the material is polymerized.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Polyester casting resin and catalyst (non-air-inhibited)
. Molds (glass tumbler, commercial glazed ceramic mold or any nonporous surface)
. Mold release (carnauba wax or polyester mold release)
. Mixing cups and sticks (tongue depressors, paper cups)
. Specimens (coins, stones, shells, bugs, etc.)
. Eye dropper

LESSON OUTLINE:

A. Select and prepare the mold
- Select proper size and shape for item to be embedded
- Mold should have minimum draft of about 5°
- Apply mold release with a rag

B. Prepare a specimen
- Clean; be sure item is dry and grease free. (Buff or polish lightly. Shine with paste wax to remove buffing compound.)
- If biological specimens are desired, prepare in accordance with instructions furnished by several suppliers. (Reference No. 4)

C. Prepare the resin
- Measure a small quantity and pour in a paper cup. (An ordinary metal kitchen measuring spoon set is desirable. Clean with acetone after use.)
- Determine proper catalyst concentration
  a. Ratio determined by layer thickness
     Thicker layers require less catalyst
  b. Consult chart provided for resin being used
     One manufacturer recommends:

1/8" layer or less	8 drops per tablespoon resin
1/8" to 1/4"	6 drops per tablespoon resin
1/4" to 1/2"	4 drops per tablespoon resin
1/2" to 1"	2 drops per tablespoon resin

- Measure out and add catalyst; mix well
- Relate method of determining catalyst concentration. Tell how thick sections of layers can crack from use of too much catalyst. Relate how rapid cures cause excess shrinkage.

D. Pour base layer
- Partially fill mold to form base layer (1/8" to 1/2", depending on size and depth of mold). Agitate mold with vibrator tool.
- Allow to gel
- Describe theory of cure of polyester resins
  a. Catalyst oxidizes the accelerator
  b. Oxidation causes heat (exothermic)
  c. Heat causes the molecules of the resin to link together forming chains
  d. Chains crosslink with other chains to form a solid

E. Add specimen
- Coat specimen with catalyzed resin to seal out air bubbles
- Place on gelled base layer
- Cover with catalyzed resin. (Light weight specimens float. Pour a thin holding layer and allow to gel.)
- Relate specific gravity information effecting specimens. Compare specific gravities of materials.

F. Pour a cover layer
- Measure, catalyze and pour layer or layers and cure
- Relate how several thin layers cause less problems than thick layers
- Relate difference between air-inhibited and non-air-inhibited resin

G. Remove from the mold
- Show how shrink will pull large castings from the edges
- Show how hot and cold water baths help release small castings
- Show how air jets can release surface tension to help pull castings

H. Trim and buff
- File and/or sand surface exposed to air and corners
- Buff (as you would acrylic plastic) if desired
- Relate that buffing is actually an abrasive operation and how it creates heat

SUMMARY:

The casting or encapsulation with polyester resins consists of a simple and well planned sequence of measuring, catalyzing, and pouring of resins into a properly prepared mold. A specimen is added, if desired. When the resin has properly cured, it has undergone a chemical change (polymerization). This material cannot return to its original liquid form.

QUESTIONS:

Q: Why does the resin become hard when catalyzed?
Q: Might the resin be hardened without a catalyst? If so, how can this be done?
Q: How does layer thickness affect cure time? What compensation is made for layer thickness in catalyzation?
Q: What is exothermic heat? Endothermic heat?
Q: What material is added to polyester resins to make them non-air-inhibited?
Q: Why must specimens be clean, dry and grease free for use as embedments?

FOAMS

Lesson		Page
30	Expandable bead foam (related)	108
31	Expandable bead foam molding (demonstration)	112
32	Expandable resin foams (related)	116
33	Expandable urethane foam molding (demonstration)	119

UNIT VII FOAMS

Lesson 30

Related Lesson: Expandable bead foam

OBJECTIVES:

. To obtain a knowledge of the development of polystyrene
. To introduce an understanding of the methods of molding foams
. To give students an insight into the many applications of the products in industry and the home

REFERENCES:

1.	Koppers Co., Inc.	Expandable Polystyrene	pp. 1-33
2.	SPI	Plastics: Story of an Industry	pp. 26-27
3.	Swanson, Robert	Plastics Technology	Chap. 10
4.	*Teach and Kiessling	Polystyrene	pp. 128-150

FOR DISCUSSION:

. Chemical and historical development
. Properties and characteristics of expandable polystyrene
. Compounding methods of the beads
. Industrial and consumer applications of expandable polystyrene

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Compare historical development of polystyrene with development of other plastic materials.
. Study various advantages, properties, and limitations of products made of polystyrene.
. Show various samples of objects molded from polystyrene heat-expanded beads.
. Experiment with the amount of expansion in various brands of polystyrene heat-expandable beads.

BRIEF DESCRIPTION OF PROCESS:

Polystyrene, in the form of foam materials, is a rapidly growing area of application in the plastics industry. Polystyrene heat-expandable beads are placed in a mold, subjected to heat, and expanded into a foam which has a closed cell structure.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Virgin beads
. Expanded beads
. Product samples - bottles, toys, sandwich panels, packing materials

LESSON OUTLINE:

I. Polystyrene chemistry

A. Production
- Coal tar and natural gas are distilled to form ethyl benzine
- Polymerization of ethyl benzine produces polystyrene

- An expanding agent is added to polystyrene beads. The styrene beads are manufactured by suspension polymerization wherein the necessary quantity of expanding agent is forced into the beads in a pressure vessel by one of a number of patented processes. The resultant product contains from 5 to 8 percent volatile material which, with the application of heat, will cause the polystyrene beads to expand to several times its original size.

B. Characteristics
- Thermal insulator. Very low thermal conductivity; (K factor examples: refrigerator parts, air conditioners)
- Water resistance. Low water absorption, less than 1% water absorption by volume. Examples: buoys, boats, buoyant chambers
- Shock resistance. Energy absorption of 61 lbs per sq. in. at a density of 1 lb per cubic foot
- Strong and lightweight. Lighter than cork and moldable at densities as low as 1 lb. per cubic foot, 1 cubic foot supporting over 60 lbs. in water

II. History

A. In 1839, the German scientist, Simon, develops styrol (little commercial value)

B. From 1839-1938, Experimentation indicated by patents issued shows that polystyrene was developed from styrol

C. In 1950's, Expandable beads are developed by large chemical companies in Germany

D. As of 1964, Expansion of use is projected in the area of automobile body construction and sandwich constructed building materials

III. Processing techniques

A. In large objects pre-expansion necessary to control density

B. Molding techniques:
- Steam chest autoclave (pressure cooker)
- Steam probe
- Conduction heating
- Radio frequency (as a source of heat, may become most popular industrial method)

C. Where pre-expansion is not necessary virgin or non-expanded beads are used

IV. Applications

A. Thermal insulation
- Refrigerator linings and storage units
- Rocketry
- Picnic coolers

B. Buoyance - boat construction

C. Core in sandwich construction - insulation, building materials

D. Low density filler - blocks, sheets, and loose fill used for packaging television tubes, meters, etc.

V. Industrial considerations

A. Production volume. Polystyrene accounted for 33 percent of the plastics volume used in 1964; an increasing amount of this volume is in the form of expanded beads

B. Industry is experimenting with auto body construction and building materials as new uses for expanded bead

VI. Consumer values

A. Picnic coolers. Thermal insulation bottles are inexpensive and lightweight with shock resistant qualities as well

B. Packaging with loose fill. Expanded polystyrene foam is more expensive than conventional materials, but the high shock resistance of the plastics material results in less breakage and lower final price to the consumer.

VII. Safety precautions

A. A low flash point creates a fire hazard. Some foams are specially compounded to be self-extinguishing.

B. Avoid breathing fumes. The blowing agent usually induced in the bead is a toxic gas. Store beads in airtight containers.

SUMMARY:

Expandable polystyrene is a thermoplastic that comes as small high density granules containing an expanding agent. When heated in a suitable mold the beads expand up to 45 times their size and fuse to form a strong, light weight plastic foam. The characteristic of the foam lends itself readily to a variety of uses.

Of the major basic materials of the plastics industry, one third of the volume is polystyrene (approximately 20 percent of polystyrene used for foams in 1963). Toxic gases and a comparatively low flash point warrant care when handling the heat expandable beads.

QUESTIONS:

Q: What impact has the development of foam had on the use of polystyrene in the plastics industry?
Q: Give five examples of articles manufactured from polystyrene heat-expandable beads.
Q: Give several reasons for the increased use of polystyrene expanded beads.
Q: What characteristics of the heat-expandable beads should be considered when handling?

UNIT VII FOAMS

Lesson 31

Demonstration: Expandable bead foam molding

OBJECTIVES:

. To introduce an understanding of the procedures followed when molding various objects by use of the steam chest method

. To acquaint students with characteristics of polystyrene heat-expandable beads

REFERENCES:

1.	Koppers Co., Inc.	Expandable Polystyrene	pp. 1-33
2.	SPI	Plastics: The Story of an Industry	pp. 26-27
3.	Swanson, Robert	Plastics Technology	Chap. 10
4.	*Teach and Kiessling	Polystyrene	pp. 128-150

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Mold from a cast or spun aluminum mold, using a pressure cooker.
. Mold from a thin walled mold immersed in boiling water.
. Mold from an aluminum foil mold, using a radiant heat source.

courtesy of The Dow Chemical Company

BRIEF DESCRIPTION OF PROCESS:

Foamed articles can be made quickly and easily using expandable polystyrene beads by heating the beads to cause expansion within a suitable confining mold.

The density of the molded article is governed by the pre-expansion of virgin beads in an unconfined manner, and careful measurement of material used to change each mold.

Steam heat is often used to further expand the beads within a mold which determines the shape and helps form a unicellular rigid foam.

MATERIALS, EQUIPMENT, AND/OR TEACHING AIDS:

. Virgin beads
. Pre-expanded beads
. Mold release (spray or heat resistant wax)
. Devices to pre-expand the beads
  - Heat lamp - radiant heater
  - Boiling water
  - Sieve fine screen
. Molding unit
  - Pressure cooker
  - Pot of boiling water
. Molds
  - Cast
  - Spun
. Pail of cold water
. Safety goggles, asbestos gloves
. Tongs

LESSON OUTLINE:

I. Pre-expanding the beads. This process is used in industry to control density when using large molds

   A. Stir beads in boiling water (will float when expanded). Then allow to cool and dry before use.

   B. Heat with radiant heaters over a variable speed traveling belt, or vary the heat source over a constant speed traveling belt

II. Molds. Spun aluminum or cast aluminum

   A. Vent holes. Drill one for every two square inches of mold area, using a number 60 drill

   B. Mold release. Apply light coat of silicone spray to interior

III. Molding

   A. Prepare a mold
   - Filling:
     a. For a thin wall section part or where surface durability is desired, use raw or virgin beads (not pre-expanded). Fill mold one-half to three-fourths full. Object will be quite hard and dense.
     b. For thick wall section part or where light weight or low thermal conductivity is desired, use pre-expanded beads of the desired density. Fill mold full.

- Close mold and fasten top securely

B. Autoclave (pressure cooker)
- Add water. Observe safety limits for unit being used.
- Bring water to boiling point
- Place mold in steaming unit
- Secure top of pressure cooker, keeping safety valves open
- Close escape valves after top has been secured
- Raise steam pressure to 15-25 psi, or within limits prescribed for unit being used. (Steaming time will vary due to wall thickness of mold and steam pressure. Try 2 minutes time after pressure reaches 20 psi.)
- Open escape valves to release steam. (Wear asbestos gloves and safety goggles.)

C. Remove mold using tongs

D. Cool mold by placing in cold water for 5 minutes

E. Open mold, remove product. Use air jet on edges if removal is difficult.

IV. Alternate methods

A. Conduction heating method. This heat source may be used for thin molds in place of steam

B. Hot water method. Thin molds may be immersed in boiling water for expansion

C. Steam chest and steam probe. This method is used in industry for thick section

V. Safety precautions

A. In handling the beads
- Toxic vapors present a hazard when bead container is opened
- Beads have low flash point and represent a fire hazard
- Keep beads off floor to prevent slipping

B. In the use of steam equipment
- Secure top
- Add water each time pressure cooker is used
- Use asbestos gloves and safety goggles
- Follow operating instructions for steam equipment being used

SUMMARY:

Polystyrene heat expandable beads may be placed in a suitable mold and moved to an autoclave (pressure cooker) for a time sufficient to cause the blowing agent to expand the bead and produce a polystyrene foam product.

QUESTIONS:

Q: How is the density of a polystyrene expandable-bead product determined in our experiment?
Q: What methods are used in industry to produce polystyrene foam products?
Q: Why are polystyrene beads pre-expanded in industry?
Q: How may we pre-expand polystyrene beads in class?

UNIT VII FOAMS

Lesson 32

Related Lesson: Expandable resin foams

OBJECTIVES:

. To develop an interest in how industry uses resin foams

. To acquaint the student with various foams used by industry

REFERENCES:

1.	Lewis, Alfred	The New World of Plastics	p. 50
2.	Redfarn and Bedford	Experimental Plastics	
3.	SPI	Plastics Engineering Handbook	pp. 137-197

FOR DISCUSSION:

. The manufacture of foams
. The application or use of foams

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Foam in place a coaster for glasses.
. Identify some objects, common to the home, that are made of foam.
. Make some polyurethane foam from polyester resin.

BRIEF DESCRIPTION OF PROCESS:

Foam plastics are resin materials in cellular or sponge form. The foam may be flexible or rigid, the cells open or closed. Foams may be expanded in a mold, expanded in place, sprayed, or extruded to achieve the desired result.

MATERIAL, EQUIPMENT AND/OR TEACHING AIDS:

. Foamed articles - packing cases, ring buoy
. Chart of foams on handout sheet

LESSON OUTLINE:

I. Science

A. Open cell. A cluster of cells, some connected to each other; not separated by a wall of plastic

B. Closed cell. A cluster of cells each enclosed by a wall of plastic; non-interconnected

C. Expanded by adding a foaming agent or blowing agent to the plastic
- Gas is blown into mix or dissolved in mix
- Heat volatizes blowing agent
- Tiny beads of thermoplastic or thermosetting resin, expandable by heat, are put into mix

D. Uniformity of cell structure
- The blowing agent must disperse throughout the mix
- The release of gas over a period of time and range of temperature should be rapid but controllable
- Select a blowing agent that is non toxic, will not develop too much heat, and will not effect rate of cure
- Check manufacturer's recommendation in selecting blowing agent

E. Foam characteristics
- Usually good heat and electrical insulators
- May be flexible or rigid
- Flexible open cell will absorb water
- Flexible and rigid closed cells will float
- Structure of walls and cells give strength to the foam
- Density can be varied

F. Safety
- Store resin and blowing agent in cool place
  Refrigeration lengthens shelf life
- Keep away from fire and flame
- Have proper ventilation. (Essential do not inhale fumes).
- Keep containers covered
- Wear gloves (disposable type is best)

II. Urethene foam, it's composition, industrial use and application

A. Made by mixing a resin, water and a isocyanate catalyst

B. Varies from flexible to rigid and therefore lends itself to a wide range of uses

C. Processes of using urethane foam
- Batch mixed
  a. Material blended thoroughly
  b. Mixed until foaming begins
  c. Poured into cavity
- Continuous metering and mixing
  a. Separate pump handles components
  b. Enough of the components pumped to fill cavity
  c. A nozzle used to inject foam into a mold
  d. Foams in the cavity
- Spray application (for thin applications)
  a. External mix guns. Catalyst is mixed into resin as it issues from nozzle.
  b. Internal mix. Catalyst and resin are mixed together before spray.
  c. Reaction starts as compound leaves gun
- Slabs (flexible and rigid)
  a. Mixing head lays down a layer of mix on release paper
  b. Expand to desired thickness
  c. Thin sheets may be slit from large slabs
- Mold forming
  a. Measured amount of foam is injected into mold
  b. Foam expands to take shape of mold

D. Application
- Flexible
  a. Seat cushions and padding
  b. Shock proofing - dash boards
  c. Insulation - pipes, homes, etc.
- Rigid
  a. Floatation - boat hulls
  b. Insulation - buildings
  c. Structural - airplanes, boats, etc.

E. Consumer values
- Cost of plastic foams is less than that of foam rubber
- Plastic foams do not deteriorate as rubber foams do
- Fire hazard is greater in urethane foams than rubber foams

III. Other plastic foams
(See chart)

SUMMARY:

A wide variety of foams are available and used in our daily life. Chemicals may be compounded to form many basic foam resins. They are open or closed cell structure and either rigid or flexible. Foams are usually good heat barriers due to low density characteristics.

QUESTIONS:

Q: Identify names of foams.
Q: What is the difference between open and closed cell foams?
Q: Where are some major foams used in day to day living?
Q: What does a forming agent do in the forming of a foam?
Q: What role does the resin in a foam play?

UNIT VII FOAMS

Lesson 33

Demonstration: Expandable urethane foam molding

OBJECTIVES:

. To show the process used in making urethane foam products

. To introduce the student to materials used in foams

REFERENCES:

1.	Edwards, Lauton	Industrial Arts Plastics	P. 129
2.	Swanson, Robert	Plastics Technology	Ch. 1,3,18

FOR DISCUSSION:

. The uses of urethane foam
. Safety precautions to be employed in working with foam

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Foam in place around a thermos type bottle.
. Make a buoy for a swimming pool.
. Make some duck decoys (vacuum formed skin, foam in place core).

BRIEF DESCRIPTION OF PROCESS:

Urethane foam is made by mixing proper proportions of resin and blowing agent. The resulting expansion causes air cells to form in the resin, giving the material its light weight, buoyancy, and insulating properties.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Urethane foam components for either rigid or flexible products
. Electric hand drill with paint mixer paddle
. Acetone for cleaning
. Containers to mix in, such as paper cups, tin cans, etc.
. One pound capacity postal scale
. Small cups for weighing components
. Rubber gloves or disposable plastic gloves

LESSON OUTLINE:

I. Pouring and mixing

A. Measure by weight (proportions of components in product instructions, often 50/50)

B. Pour components together

C. Mix with electric drill for from 10 to 30 seconds. (Read instructions and experiment with each resin used.)

D. Pour into mold or form
. Let foam set for approx. 5 minutes
. Foam achieves full strength in approximately 24 hours

II. Safety

A. Work under exhaust fan. Avoid breathing vapors released during foaming.

B. Keep resins away from fire and flames

C. Wear rubber, or disposable plastic gloves

D. Wash foam off tools and hands before it sets, using acetone or lacquer thinner, followed by soap and water. (Acetone will dissolve foams after setting.)

SUMMARY:

Foams have opened new horizons; we may now add buoyancy, insulating, or cushioning qualities to products as needed.

QUESTIONS:

Q: Where can we use rigid urethane foam?
Q: Where is flexible urethane foam used primarily?
Q: What makes a plastic foam expand?

UNIT VIII COATING

Lesson 34

Related Lesson: Coating processes

OBJECTIVES:

. To develop an understanding of coating processes in commercial use

. To investigate occupational-industrial potentials

. To develop an understanding of basic coating materials

REFERENCES:

1.	Bakelite	The ABC'S of Modern Plastics	p. 12
2.	Simonds and Church	Concise Guide to Plastics	pp. 66,83,87, 163,165,203,205
3.	*SPI	Plastic Engineering Handbook	pp. 250-270

FOR DISCUSSION:

. Major uses of plastic coated products
. Occupational industrial potentials of plastic coatings
. Products and respective coatings

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Dip coat a project (hot or cold).
. Upholster with vinyl fabrics.
. Take a field trip to a coating plant.
. Make a mock up of a coating mill.
. Try coating various kinds of cloth and assorted coating materials.

BRIEF DESCRIPTION OF PROCESS:

Coating processes are methods for applying a film or thin layer of plastic to an item. This covering serves three purposes:

- To protect
- To decorate
- To reduce vibrations (optional)

Which of the coating processes are to be used is determined by the following:

- Type of material or item to be coated
- Type of coating material to be used
- Equipment available and/or location of application

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Samples of as many coated products as are available
. Pictures and/or charts depicting coating principles

LESSON OUTLINE:

I. Definition and purpose of coating

A. Controlled application of a mobile film forming material
B. Protective, decorative, and vibration dampening

II. Coating developments

A. Coating applications developed during World War II to protect electronic components and wires in severe environmental conditions

B. Other developments in response to need for material protection from damage in handling, storage and in-motion vibration

III. Basic Materials Coated with Plastics

A. Paper - milk carton
B. Fabric - window shade
C. Metals - tool edges and high exposure products
D. Wood - paints

IV. Plastic Coating Resins

A. Melamine
B. Vinyl
C. Polyamide (Nylon)
D. Epoxy
E. Styrene
F. Polyethylene
G. Alkyds (major use is coating)
H. Polyesters (200 million lbs. used in 1961)
I. Phenolics
J. Ureas
K. Cellulosics
L. Acrylates
M. Silicones
N. Fluorocarbons
O. Polyurethane
P. Elastomers

V. Basic Coating Processes (see diagrams)

A. Painting - use of brush, roller or spray gun

B. Dipping
- Hot dipping - cushion grip on plier handles
- Cold dipping - protective coating on edge tools

C. Fluidized bed-coated - chain

D. Vacuum metallizing - dash board parts

E. Electroplating - light reflectors

F. Silk screening on package decoration

G. Calendering spread coating and roller coating-vinyl fabric, milk cartons, etc.

H. Flame spraying prototype work

I. Extrusion coating wire insulation

J. Calendering as a sheet forming process - flat sheet stock for vacuum forming, etc.

VI. Scope of plastic coating in industry

A. Approximately one fourth of all resins produced are for coating

B. Job opportunities
- In small business house painters, silk screening, etc.
- In major manufacturing
  a. Mostly semi-skilled labor
- Industrial development job potentials
  a. Substantial need for industrial research
  b. The major growth area in polyesters, the versatile unsaturated types in particular

SUMMARY:

Many manufacturers consider the final consumer product as their largest market area with great financial promise. Therefore, coatings which protect, reduce vibration and/or beautify the final product are given careful consideration. Often new processes have had to be developed to take full advantage of new materials brought about by chemical research. There is an opportunity for both large and small businesses to use plastic coatings.

The use of polyesters as a coating material appears to have great potential. Alkyds as used in paint are the dominant plastics used today. The use of new materials for new jobs keeps the market for coated materials expanding.

QUESTIONS:

Q: Describe what is meant by a plastic coating.
Q: List and describe the basic plastic coating processes.
Q: Why should we be informed as to the coating possibilities of each coating resin?
Q: Describe five products which are plastic coated, and tell why they are coated.
Q: Name five basic materials which are coated with plastics.

UNIT VIII COATINGS

Lesson 35

Demonstration: Cold dip coating

OBJECTIVES:

. To show the industrial process for protective coating of tool edges

. To develop an understanding of the simple industrial process which utilizes cellulose acetate butyrate

REFERENCES:

1. Eastman Chemical Co. "Peelable Plastic Packaging" Film
2. Eastman Chemical Co. "Peelable Plastic Packaging" Brochure

FOR DISCUSSION:

. World War II utilization of this coating process
. Products presently sold with this coating

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Coat a sharp tool cutting edge.
. Coat a machine part (possible student project).
. Experiment with varying temperatures for desired coating thickness.
. Coat cutting edges of shop tools at close of school year.

BRIEF DESCRIPTION OF PROCESS:

Cold dipping in cellulose acetate butyrate is accomplished by preheating the cellulose acetate butyrate (350° to 375° F) and dipping a metal object into the hot liquid. Remove the object from the liquid, and a coating of plastic material will solidify around the cooler object. The cellulose acetate butyrate provides protective qualities of three types: 1. lubrication of contacting surfaces; 2. masking of cutting edges; and 3. dampening of vibration.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Cellulose acetate butyrate dipping compound
. Heating pot (1/2 to 1 qt. capacity, minimum)
. Heating element with temperature control
. Probe type thermometer
. Chisel or other object to be coated
. Cleaning materials (greaseless solvent, steel wool, etc.)
. String or wire to use as dipping holder
. Shop apron and gloves

LESSON OUTLINE:

I. Prepare object for coating

A. Be sure object is properly made, sharpended, etc.

B. Clean before coating
- Wipe off all finger prints
- Dip in solvent, or steel wool the area to be coated
- Fasten dipping wire to object
- Suspend to keep clean

II. Set up coating equipment

A. Preheat pot of cellulose acetate butyrate to 350° F (Note: this is a thermoplastic material, and overheating may cause burning.)

B. Have work station clean; provide a dripping area for cooling

C. Protect clothing; wear apron and disposable gloves

III. Perform cold dip coating

A. Place clean tool (or portion thereof) in heated plastic

B. Agitate slowly to coat all areas

C. Remove slowly, drip excess in pot

D. Hang in a safe area to cool

IV. Complete coating process

A. Place drippings from floor back in hot pot

B. Turn off heating element

C. Label area as "hot"

V. Maintain safety precautions

A. Use electric heating element only (no open flames)

B. Ventilate area during process

C. Use extreme care in handling heated plastic

D. Protect clothes and hands from drippings or spills

SUMMARY:

The cold dipping process using cellulose acetate butyrate compound has the following characteristics:

- Completely seals surface from weather
- Lubricates metal surfaces coated
- Protects cutting edges and dampens vibration

This economical process, using low heat, lends itself to both large and small industrial applications. A major advantage is the characteristic of the cellulose acetate butyrate whereby it may be reheated many times. Product applications include coating machine tool edges or machined areas, parts and cutting edges, or as a substitute for masking tape when painting only a portion of a product.

QUESTIONS:

Q: What is the name of a plastic material used as the coating in the cold dip coating process?
Q: What are some practical applications of cold dip coating?
Q: Describe the procedure for cold dip coating.
Q: What safety precautions are to be taken in cold dip coating?

UNIT VIII COATING

Lesson 36

Demonstration: Fluidized bed coating

OBJECTIVES:

. To demonstrate the process known as fluidized bed coating

. To acquaint students with a hot dipping process

3.	Swanson, Robert	Plastics Technology	pp. 322, 323
4.	U.S. Industrial Chemicals	Microthene Polyethylene Powder Info. sheet	Ch. 2A

FOR DISCUSSION:

. Factors involved in powder coating with various types of plastics
. Commercial products presently coated through fluidized bed process
. The kinds of material used for fluidized bed coating

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Coat a cold chisel, center punch, or other metal project.
. Test samples of coating materials using variables which might include:
  - Material to be coated
  - Coating material
  - Time required in fluidized bed
  - Time required to pre heat and post heat object
. Experiment with the use of different materials for the porous base plate of the fluidizing chamber.
  - Felt pad
  - Leather
  - Styrofoam
  - Cellulose sponge
  - Others

Fluidized Bed Coating

PRIME

PREHEAT

courtesy of Eastman Chemical Products, Inc.

BRIEF DESCRIPTION OF PROCESS:

Plastic coatings can be applied to other materials by dipping preheated objects into a bed of plastic powder made fluid by a flow of air. This process is called fluidized bed coating. The hot object (about 200° to 500° F) picks up a coating by partially fusing a powder on the hot surfaces. The coating is then post heated in order to smooth and completely fuse the plastic.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Heating device - hot plate, copper enamel kiln
. Thermometer (to 500° F)
. Clear or colored coating material - polyethylene or butyrate powder
. Fluidizing chamber (see sketch P. 3, microthene booklet)
. High volume, low pressure air source (2 to 5 psi. approx.) - compressor, vacuum cleaner, etc.
. Metal item to be coated
. Dipping wire
. Cleaning materials - steel wool, abrasives, solvents such as acetone, etc.

LESSON OUTLINE:

I. Purpose of coating

A. To protect from corrosion
B. To decorate
C. To reduce vibration

II. Advantages of fluidized bed process

A. It lends itself to production line work

B. Setup cost is low
- A controlled coating can be applied
- Coatings are durable and can be colored
- Coating has strong bond to object

C. Only material in contact with the job is used. No material is wasted.

POSTHEAT

III. Process procedure (Check manufacturers specifications for exact instructions.)

A. Set up equipment
- Activate heating source (200° F to 530° F)
- Fill fluidizing chamber
- Open air supply valve until air bubbles are uniform in size
- Hook dipping wire to object

B. Preclean object
- Clean physically with steel wool
- Use a chemical cleaning agent and let dry

C. Preheat object
- Place over heat source or in oven
- Check temperature with thermometer until desired heat is reached

D. Coat object
- Carefully dip object in fluidized bed of powder
- Remove object for postheating

E. Postheat object to fuse
- Suspend coated object over heating source or in oven
- Watch for smooth flow of material on object
- Be careful not to overheat and burn coating

F. Clean up area
- Turn off heating element and label the area "hot"
- Place unused coating material in air-tight container

SUMMARY:

The fluidized bed coating process can be applied to any shape or size of object with a low initial setup cost.

A high quality, uniform finish, which is protective, decorative and vibration dampening is achieved on any object to be coated by the process. All objects coated must be able to withstand the pre-and-post-heating operations.

QUESTIONS:

Q: Describe the fluidized-bed coating process.
Q: What are the basic coating materials used in hot dipping, and describe their characteristics?
Q: Describe the advantages of the hot dip coating.
Q: Why does industry utilize the fluidized-bed process?
Q: What is the difference between hot and cold dipping?

UNIT VIII COATINGS

Lesson 37

Related Lesson: Vacuum metallizing of plastics

OBJECTIVES:

. To develop a knowledge of the vacuum metallizing process

. To show the student illustrations and examples of the process

REFERENCES:

1. Bee Chemical Co. "Why and How of Vacuum Metallizing" Finishing News Magazine, reprint

2. Gilbert, M. B. and Garwood, A. D. "Vacuum Metallizing" Modern Plastics Encyclopedia 1963 p. 859

3. Narcus, Harold Metalizing of Plastics

4. Thorson, M. L. "The Art of Plastics Decoration" SPE Journal, Vol. 17 Nov. 12 - Dec. 61

FOR DISCUSSION:

. Describe the previous uses of vacuum metallizing
. Give a brief description of the process as it exists today
. Illustrate some of its applications
. Illustrate some possible future uses of this process

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Make a large poster illustration of the process.
. Make a colorful display of vacuum metallized parts.
. Have students make up product folders on this process.

BRIEF DESCRIPTION OF PROCESS:

Vacuum metallizing is a process in which surfaces are thinly coated with metal by exposing them to a vapor of metal that has been evaporated under vacuum of one millionth of normal atmospheric pressure. The vaporized metal condenses on the surface of the plastic.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Flow chart of the vacuum metallizing process
. Picture of the process
. Samples of vacuum metallized plastics

LESSON OUTLINE:

I. The Process

A. Procedure
- Part to be coated is cleaned in a detergent
- Lacquer base coat is applied
- Parts are placed on a holding fixture and placed in a chamber
- The pressure is reduced in two stages
  a. Rough pumping of vacuum is brought down to 100 to 200 microns (0.1 to 0.2 MM mercury or .002 to .004 inches of mercury.)
  b. The diffusion pumping of vacuum is brought down to 0.3 or 0.5 microns (0.0003 to 0.0005 MM mercury or 0.000,007 to 0.000,001 inches of mercury), at this point 99.9999 percent of the air has been removed from the vacuum chamber.*
- The metal is heated an evaporation or vaporization takes place
- The metal condenses on the plastic part
- Atmospheric pressure is restored
- A final coat of lacquer is applied

B. Equipment
- Vacuum metallizers have four major components
  a. Vacuum chamber capable of being evacuated to a pressure of 0.5 micron or lower
  b. Pumping system having
     Roughing pump
     Holding pump
     Oil diffusion pump
     Pump cooling system
  c. Holding fixtures to go into chamber
  d. Heating device for evaporation of the metal
- Lacquering equipment to apply by spray, dip or brush
- Baking oven
- Cleaning equipment

C. The metals used and their vaporization temperatures under vacuum

Aluminum	1000°F
Copper	1270°F
Gold	1460°F
Silver	1050°F
Zinc	340°F

II. The Product

A. Types of objects metallized
- Molded parts use vacuum chamber method with a 10 to 20 minute cycle
- Films use continuous metallizers in which continuous web stock enters and leaves through vacuum seals

B. Selection of surface to be coated
- Front or outside surface least desirable. Can be scratched easily
- Underside of clear plastic preferred. Plastic protects the metallized surface from being scratched

---

*1 micron = 0.001 MM mercury or 0.00002 inches of mercury

C. Advantages of vacuum metallizing
- Applies corrosion resistant surface
- Lengthens service life
- Decorates surface
- Makes undesirable colored plastics parts usable
- Utilizes scrap plastic
- Eliminates undesirable properties of certain plastics
- Has the inherent properties of the plastic plus the desired properties of the deposited metal

D. Disadvantages
- Industrial equipment costly. Need equipment for coating, lacquering and curing finished jobs
- Time, labor, materials and extra processes add to the cost
- Vacuum metallizing often jobbed out to specialty shops

III. Applications of vacuum metallizing

A. Present
- Plastic automotive fabrics
- Draperies
- Food preparation papers
- Papers for printing and publishing
- Electrical insulators (plated with copper, cadnium or lead)
- Printed circuits
- Aviation parts (retards vibrations)
- Resistors, condensers, and relays
- Ceramics, glass, quartz and other materials

B. Future
- Glare reducing coating on aircraft windshields
- Defrosting of aircraft windows
- Sun glasses (optional interference)
- Complex electronic circuitry

SUMMARY:

Vacuum metallizing is a process which is readily adaptable to mass production. It provides low cost parts which resemble those made from metal. It is a process which is finding a larger application in the plastics industry.

QUESTIONS:

Q: Why are plastic products vacuum metallized?
Q: What is the importance of rotating the plastic part during the metallizing cycle?
Q: Why is it more practical to metallize parts on the second surface than the first?
Q: Why must most plastics be lacquered before metallizing?

C.109203

UNIT VIII COATING

Lesson 38

Related Lesson: Electroplating plastics

OBJECTIVES:

- To develop an understanding of the process of coating a non-conductive plastic object with metal
- To present the industrial and consumer applications of metal plated plastics

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

- Compare electroplated samples with vacuum metallized products, and discuss limitations of each process.
- Discuss current and future applications of the electroplating process.

PLATING MARKETS FOR ABS - 1964

END USE	TOTAL ABS Millions of lbs.	PLATED ABS Millions of lbs.
Automotive	22	1.8
Appliance and business mach.	12	1.0
Other moldings	10	0.5

The above table reproduced from - S.P.E. Journal, April 1964, p. 309

COS 204

BRIEF DESCRIPTION OF PROCESS:

A process in which a conventional metal plating (chromium, copper) is applied to a plastics part, the surface of which must first be made conductive.

LESSON OUTLINE:

I. History

A. In the 1940's, plastic bottles, etc. first electroplated for the military

B. In the 1950's, metal covered fillers for costume jewelry and household gadgets were developed; there was also some unsuccessful experimentation with tetraflouroethylene resin (TFE)

C. In 1960's
- Decorated automobile parts
  a. Letter ornaments
  b. Turn signal handles
  c. Door lock buttons
- Printed circuitry - through-hole plating process

II. Materials adaptable to process

A. High impact polystyrenes
B. Acrylonitrile-butadiene-styrene (ABS) materials
C. Urea formaldehydes and phenol-formaldehydes
D. Others

III. Applications

A. Printed circuitry
B. Automotive-name plates, radio and clock cover plates, rear view mirror frames
C. Appliances - control knobs, vacuum cleaner heads, handles, buttons
D. Plumbing - faucet handles, drain flanges, plugs, sink strainers
E. Other home and industrial - false teeth, thumb tacks, pen barrels, marine hardware levers and handles

IV. Industrial plating process

A. Pretreatment and cleaning of the insulator surface with organic or detergent solutions by:
- Barrel tumbling - sand blast
- Flush method
- Ultrasonic method

Caution: Cleaning method used must not impair the insulating properties of the plastic when preparing printed circuit boards.

B. Sensitizing. (Process originated with silvering of mirrors.)
- This is a process whereby a very thin metallic film, which acts as a catalytic surface for the metal to be added, is placed on the plastic surface by means of bath or spray.
- Salts of tin, titanium, silver, gold and palladium formulations are the most widely used materials for sensitizing.

30205

C. Electroplating. Copper, nickel, gold or chromium may be used; follow conventional electroplating methods (demonstration)

D. Safety considerations
- Vapors from bath (insure proper ventilation). Do not inhale fumes.
- Electrical connections
- Wear rubber gloves, prevent contact with skin

V. Industrial outlook

In recent years the cost of electroplating has decreased due to refinements in sensitizing techniques. During the past year plastics have been used in many areas of automobile production.

It is estimated that 5 million pounds of ABS will be plated for automotive purposes in 1965. Refer to table on page 134.

VI. Guidance information

Electroplating of metals has been carried on as a separate operation in most large industrial firms for many years. Plastics may be plated by the same basic process with the addition of sensitizing equipment. No appreciable increase in occupational opportunities in this area in the near future is expected.

SUMMARY:

Electroplating is the electrochemical process of coating an object (in this case a non conductor) with metal. This method is another of the finishing and decorating approaches that a plastic customer may choose. Plastics electroplating is made possible by the use of a sensitizing operation in which an insulating material receives a conductive coating. In the electroplating of plastics, ABS plastics and high impact polystyrenes are the most common plastics materials coated.

QUESTIONS:

Q: Name three examples of electroplated plastic products.
Q: Why is sensitizing necessary when electroplating plastics?
Q: What plastic materials are best suited to the electroplating process?

20206

UNIT VIII COATING

Lesson 39

Demonstration: Electroplating plastics

OBJECTIVES:

. To demonstrate the process of applying an electroplated surface on a plastics product

REFERENCES:

1. *Marbon Chemical Div. Borg Warner	Plastics Memo #606A	
2. Narcus, Harold	Metallizing of Plastics	pp. 121-129
3. *Schlabach, and Rider Washington, W. Virginia	Printed and Integrated Circuitry (McGraw-Hill)	pp. 141-144
4. SPE	Society of Plastics Engineers Journal Vol. 20 #4, Apr. 1964	pp. 305-10

FOR DISCUSSION:

. Applications of electroplating in the automobile industry
. Limitations of electroplating process in the field of plastics

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Compare vacuum metallizing with the electroplating process.
. Electroplate ABS plastics products.

BRIEF DESCRIPTION OF PROCESS:

A very thin, fine grained, conductive film of copper is chemically deposited on, and bonded to, a plastic surface. This film provides a base upon which such metals as copper and chromium can be electroplated to form a protective, decorative finish.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Cleaner Solutions (Enthone) or equiv.
Follow manufacturer's directions carefully
. Activator Solutions (Actane, Enthone) or equiv.
. Sensitizer Solutions (Enplate) or equiv.
. Copper Bath (Enplate) or equiv.
. Disposable plastic gloves
. Electroplating Unit

LESSON OUTLINE:

I. Electroplating process

A. Surface preparation
- Immerse product in Enthone cleaner solution for 2-3 minutes
- Rinse with water
- Immerse in activator Actane solution for 15 seconds to 2 minutes

802 207

- Rinse with water
- Immerse in Enthone solution for 1 hour at 145-150°F
- Rinse thoroughly with water

B. Surface activation
- Immerse in Enplate sensitizer solution for 1 minute
- Rinse with water until all of the sensitizer solution has been removed
- Immerse in Enplate solution for 30 seconds
- Rinse with water

C. Chemical deposition of copper
- Immerse surface activated ABS in Enplate solution for 20-40 minutes
- Rinse with water
- Transfer to electroplating bath immediately

D. Electroylic deposition of copper
- Immerse product in Enplate solution until desired thickness is obtained

E. Mechanical polishing
- Polish the soft copper film to a bright luster by wheel buffing
- Clean with Enthone to remove all traces of polishing compounds
- Rinse with water
- Dip in Hydrochloric Acid solution to remove copper oxides
- Rinse with water

F. Electrolytic deposition of metal finish
- Use conventional plating techniques, treating prepared plastic product as you would any other metallic material
- Follow directions prescribed for electroplating unit available

II. Safety precautions

. Wear disposable plastic gloves
. Check insulation on all electrical equipment used
. Check manufacturers' safety precautions for all chemicals and equipment being used

SUMMARY:

The plating process for ABS plastics requires special surface preparation and surface activation to make it a conductive surface before conventional electrolytic deposition of metal and buffing take place. Care must be exercised when handling chemical solutions and electrical equipment.

QUESTIONS:

Q: Why is a thin metallic film placed on any plastic prior to electroplating?
Q: List several metallic finishes that can be placed on plastics products by use of the electroplating process.
Q: List three safety precautions which should be followed when electroplating.

FOR DISCUSSION:

. Release papers used in sheet casting
. Equipment necessary for rotational molding

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Mold an article by rotational casting.
. Discuss the types of molds used for various processes involved.
. Slush mold an article.

210
COS

BRIEF DESCRIPTION OF PROCESS:

Thermofusion involves the use of solid thermoplastic powders and/or molding granules. Vinyl dispersion resins are liquids with finely divided particles of the plastic in suspension in a plastisol or organosol.

Either material may be used for several molding methods described here.

Heat is used to cure the thermofusion powders, or to evaporate the plastisol or organosol leaving a molded part.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Molds for rotational, slush and closed molding. Consider use of metal cooking molds.
. Sample products formed by this process
  - Toys, balls, doll heads
  - Industrial chemical bottles
. Plastic materials
  - Vinyl plastisol
  - Vinyl organosol
  - Polystyrene granules and powder
  - Polyethylene granules and powder

LESSON OUTLINE:

I. Materials used

A. Vinyl dispersions. Vinyl resin is suspended in a non-water liquid which does not dissolve the resin at ordinary temperatures.
  - Vinyl plastisol. If the dispersing liquid consists only of a plasticizer, the dispersion is termed a plastisol. A plastisol, to be converted to a usable form, must be heated to fuse the resin and the plasticizer.
  - Vinyl organosols. If the dispersing liquid contains a volatile solvent, the dispersion is termed an organosol. An organosol, to be converted to a usable state, requires the evaporation of the solvent from the solution and the fusing of the resin with the plasticizer.

B. Polyethylene powders for thermofusion in rotational slush molding
  - Finely powdered polyethylene is successively plasticized, molded and then cured in the mold
  - Thermofusion powders are relatively low in cost
  - Equipment formerly used for plastisols can be employed
  - Products made with thermofusion powders offer high chemical, electrical and mechanical resistance

C. Polystyrene in finely powdered form produces clear moldings in thermofusion, as contrasted to milky colored moldings produced through use of polyethylene.

D. Polystyrene and polyethylene pellets or granules are used for solid castings. They are not suited to most rotational or slush moldings.

S1241

II. Molds should be made of a heat conducting material such as copper or aluminum

A. Molds may be made by
- Electro-deposition
- Sprayed atomized metal
- Die cast metals
- Sand casting
- Metal spinning

III. Molding processes

A. Slush molding
- Open top mold filled with plastic material
- Heated mold causes thin layer of plastic to form next to wall of the mold
- Excess material not fused to wall of mold is poured out forming a hollow, thinwalled flexible object

B. Rotational molding by Engel Process (a slush technique)
- Closed molds are filled with polyethylene powder or vinyl dispersions
- Mold is closed with a thermo insulating lid
- Filled mold is placed in a heated oven
- Layer of material is formed next to wall of mold. The thickness is determined by the temperature of the oven, the heating time and special properties of the material
  . Polyethylene plasticizes
  . Vinyl dispersions fuse
- After heating cycle of 4 to 5 minutes the excess plastic is poured out
- Mold is returned to the oven to smooth insides
- After mold has cooled the product can be removed from the mold
- Industrial considerations
  . Product usually limited to open end type
  . Limited runs up to 8500 units are practical
  . Longer runs could be done less expensively by injection molding unless product is too large
- Consumer considerations. Tanks, bottles, toys and other flexible items are produced by this method.

C. Rotational method by the Heisler process (centrifugal hot mold method - a slush technique)
- Used to produce hollow objects with one or two open ends such as pipes or tubing
- Mold is preheated to 325 to 365 degrees F, and partially filled with plastic material
- The filled mold is rotated in an oven on a single axis or plane until material fuses and forms a shell on mold walls
- Excess material is poured out and mold is cooled before product is removed
- It is a slow process unless highly automatic techniques are adopted for high production

1212

D. Rotational molding using polyethylene powder
- Enough powder is placed in mold to coat sides to the desired thickness
- Mold is heated to 300 to 400 degrees F
- Mold is rotated on 2 planes or axes for approximately 5 to 10 minutes. The polyethylene powder plasticizes in this phase of the operation after which the mold is cooled and product removed.
- Rotational molding is a practical industrial process
  . There is little waste or scrap
  . There is no dumping of excess powders as in slush casting
  . The process is easily adapted to continuous high production methods
- Product characteristics
  . Has uniform wall thickness due to two plane rotation
  . Products strain free hollow parts

E. Rotational molding using vinyl dispersions
- Vinyl plastisols or organosol is used in similar manor for polyethylene powder
- Plastisols fuse at 300 to 375 degrees F
- Industrial and product considerations similar to powder rotational casting

F. Solid casting with either polyethylene powder or polystyrene powder
- Powdered material is placed in mold
- Decoration in form of glitter or tinsel can be added
- After resins are plasticized in hot oven the mold is removed and cooled before part is removed
- Equipment cost is low. Sheet metal or cast molds can be used.
- Intricate shapes can be molded with ease using a low cost thermoplastic material

G. Casting with vinyl dispersions
- Vinyl dispersions are measured on release paper then heated to 300 to 400 degrees F when dispersion fuses
- A flexible sheet of plastic is formed
- Used primarily to make experimental samples. Often laminated to cloth for clothing, coats, etc.

IV. Industrial considerations

A. Advantages of thermofusion and plastisol molding
- Large objects may be produced inexpensively
- Molds are inexpensive to make compared to injection molds and others used
- There is little waste of plastic materials involved in this process
- Materials cost less than those using sheet stock
- Hollow flexible objects may be molded in one or two pieces

B. Disadvantages of thermofusion and plastisol molding
- Long runs become more expensive due to labor. Extremely large items still cheaper.
- Only thermoplastic materials can be used
- Slush casting requires dumping excess material out of mold

C. Applications
- Slush casting (hollow articles with open end)
  . Tanks for chemicals
  . Sporting equipment
  . Toys
- Rotational molding (hollow, closed or open articles)
  . Industrial bottles
  . Toys - hobby horses
  . Doll heads
  . Balls
- Solid castings
  . Printing plates
  . Auto mats and arm rests
  . Decorations, craft items
  . Encapsulation of electrical parts

SUMMARY:

Thermofusion of powdered plastics and fusion of vinyl dispersions has opened new ways of producing a better product for a lower cost. New materials and new fabricating processes are making possible a variety of new products which are appearing on the consumer market almost daily. The product and its application govern whether the rotational, slush or solid molding technique will be used.

QUESTIONS:

Q: How do rotational, slush and solid molding differ?
Q: What is a vinyl dispersion?
Q: How do products made from vinyl dispersions differ from products made from polyethylene powders.
Q: Name two types of vinyl dispersions.
Q: Why are molds for rotational molding less expensive than molds for injection molding of the same hollow article?

214

UNIT IX VINYL DISPERSION - THERMOFUSION

Lesson 41

Demonstration: The molding of a vinyl dispersion

OBJECTIVES:

. To demonstrate several techniques of molding with vinyl dispersions

. To show to the student applications of this process

REFERENCES:

1.	Howard and Markwood	"Cast in Textures for Vinyl" Reprint Modern Plastics	Nov. 1963
2.	SPI	Plastics Engineering Handbook	pp. 270-278

FOR DISCUSSION:

. The major methods used to mold parts through use of vinyl dispersions
. The variety of products available made from vinyl dispersions
. Possible future development of new products using vinyl dispersions

EXPERIMENTAL AND/OR PROJECT ACTIVITIES

. Prepare a display of products made from vinyl dispersions.
. Design and mold individual projects using a vinyl dispersion.
. Investigate the variety of differently shaped molds available and mold with them.

Schematic Diagram of a Conveyerized Slush-Molding Setup. Variable speed chain drive, oven thermostats, and cooling water controls are desirable.
courtesy of The Society of the Plastics Industry, Inc.

BRIEF DESCRIPTION OF PROCESS:

Molding with a vinyl dispersion changes a liquid to a solid material. Finely powdered vinyl is suspended in a plastisol or an organosol. Fusing the plastic with the plasticizer at about 350° F. causes the liquid to cure to a solid state. The molding processes used are similar to ones employed for the thermofusion of powdered polyethylene.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

- Compounded vinyl plastisol or organosol
- Mixing containers, (paper cups)
- Mixing spatula (coffee stirring sticks, etc.)
- Heating oven. An air circulating type such as a kitchen oven, commercial oven or infra-red heat lamps, etc. CAUTION: Do not use open flame.
- Various types and shapes of molds - jello molds, cookie tin, spun aluminum, machined aluminum molds, etc.
- Treated paper
- Heat insulating gloves
- Supporting sheet to transport mold
- Mold release - silicone spray or wax

LESSON OUTLINE:

I. Types of castings using vinyl dispersions

A. Slush molding produces a hollow shell of cured plastic next to the mold surface. Extra plastic material not fused is poured out of the mold when desired wall thickness is achieved.
B. Solid cavity molding can use mold similar to ones used for slush casting. Solid object is produced by fully curing plastic placed in the mold.
C. Sheet casting employs shallow or flat molds

II. Mold types and preparation

A. Molds may be thin walled metals like jello molds, cookie sheets, cookie molds or textured metals for leaves, etc.
B. Thicker walled molds, holding more heat can be made of cast or machined aluminum, ceramics or metals
C. All molds should be smooth and free of defects
D. Molds should be treated with a release agent such as silicone
E. The thickness of the mold, and its temperature govern the heat transferred to the plastic being formed

III. General molding procedures using vinyl dispersions

A. Place mold on supporting sheet to transfer to oven
B. Spray mold surface with silicone release agent
C. Stir the prepared plastisol or organosol
D. Start pouring dispersion into the corner of the mold. Fill to the proper level.
E. Place mold and supporting sheet in oven heated to 350° F
- Curing time will depend on mold thickness, wall thickness desired and type of product being made. See more specific instructions.
F. Remove mold from oven and allow to cool before stripping mold
- If part crumbles or tears easily, it has not cured sufficiently

IV. Slush molding special procedures

A. Prepare mold and dispersion
B. Cover top of mold with insulating lid. An asbestos sheet is satisfactory
C. After 1 or 2 minutes in oven, remove mold from oven and pour out uncured plastisol or organosol

D. Place mold (without cover) back in oven for final curing
E. Final cure has been achieved when plastisol appears glossy

V. Solid cavity molding special procedures

A. Prepare mold and dispersions, fill mold
B. Heat from 5 to 8 minutes. If article is not fully cured continue heating. Avoid over heating which causes scorching.

VI. Sheet casting

A. Prepare mold and dispersion. Treated papers can be used as mold
B. Place mold in oven for 3 to 4 minutes at 350° F. Thin sections require careful control of time and temperature

VII. Typical applications

A. Slush castings
- Movable parts for dolls
- Insert tank linings
- Electrical insulation
- Plier handles
- Gaskets for glass container covers
- Toys and boats

B. Solid Cavity Molding
- Bases such as flag standards
- Shock absorbing blocks
- Coasters for tumblers

C. Sheet Casting
- Leaves for planters
- Decorative articles
- Carpeting
- Coverings to protect finishes
- Coatings

SUMMARY:

Vinyl dispersions are easily handled and safe to work with. Only a small amount of inexpensive equipment is needed to produce numerous useful and decorative articles. Necessary molds are easily made. Economical use is made of an inexpensive material. The low cost of equipment and material necessary is usually passed along to the customer who gets a decorative item at a reasonable price.

QUESTIONS:

Q: What are the three major processes used in producing products from vinyl dispersions?
Q: Name a factor that determines the size of a part which can be made?
Q: Why are two heating cycles necessary with a slush casting?
Q: What are some similarities between molding process using vinyl dispersions and those using powdered polyethylene for thermofusion?
Q: How can one tell whether a molded part was cured if a temperature gauge was not available in the oven?

UNIT IX VINYL DISPERSION - THERMOFUSION

Lesson 42

Demonstration: Thermofusion molding

OBJECTIVES:

. To demonstrate the techniques of molding by the thermofusion of pellets or powdered polyethylene

. To give the student insight into possible other applications of this process

REFERENCES:

1.	Cherry, Raymond	General Plastics, 4th Ed.	Ch. 27
2.	Pearson, Hazel	Creating with Cooking Crystals	p. 717
3.	Redfarn and Bedford	Experimental Plastics	p. 64
4.	St. Louis Crafts, Inc. 15 W. Moody St. St. Louis, Missouri	Crafts-Maid Memos	

FOR DISCUSSION:

. Molding processes that can be accomplished in an industrial arts laboratory
. Materials used for thermofusion molding
. The use of polyethylene in combination with other materials

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Select and arrange samples made by the thermofusion process.
. Make up a display board showing a flow chart of the thermofusion process.
. Make up give aways for PTA's, etc.

BRIEF DESCRIPTION OF PROCESS:

Thermofusion of thermoplastic powders or pellets in various forms provides interesting applications in the industrial arts shop. In processing, pellets or powdered polyethylene are placed in a mold and set on a support (cookie sheet tin). The entire unit is placed in an oven and heated to the proper temperature. The fusion of the powder by application of heat will cause it to take the shape of the mold. Interesting projects of this kind can be done successfully in the shop.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Various types of molds - pizza pans, copper salad molds, cookie sheets, aluminum pans, gelatin molds, etc.
. Powders - clear and colored polyethylene
. An electric oven with a maximum temperature of 400° to 500°. An oven such as a commercial oven, domestic kitchen oven, roaster or infra-red oven could be used.

. Embedding materials - coins, metal parts, etc.
. Supporting tray - cookie sheet, metal tray, etc.
. Files and/or buffer
. Knife

LESSON OUTLINE:

I. Preparation of mold

. Select metal mold and desired polyethylene, powder or pellets
. Apply mold release (silicone spray or carnauba wax)
. Preheat oven to between 350° and 400°F
. Place mold on supporting sheet, making sure the mold is free from blemishes to insure a smooth surfaced product

II. Molding by thermofusion

A. General molding procedures
- Select and prepare mold
- Completely cover bottom of mold with a 1/8 inch thick layer of powder
- Place mold in preheated oven. Fusing time will vary depending on mold thickness and type of oven. Check frequently. Do not overheat.
- Correct heat and time are indicated when the plastic has fused together smoothly
  . A rippled effect is achieved by under fusing
  . For a smooth effect, heat longer
- Remove mold and cool in air or under a spray of water
- Rough edges should be smoothed using a fine file, sandpaper, jeweler's sanding wheel or a heated kitchen knife

B. Embedding articles in a mold
- When embedding, select items that will not melt at the fusing temperature of the plastic
- Prepare mold as before and preheat oven
- Place a 1/8 inch thick layer of clear powdered plastic in the mold
- Place material to be embedded over base layer as desired. Embedding material may be stones, glass, woodchips, metal, or colored plastic pellets.
- Place another layer of clear powdered plastic on top
- Place in oven to heat and cure as before

C. Adding color to plastic powder
- Break up colored chalk into bits
- Measure clear powdered plastic in another container, and add colored chalk to it
- Shake until color is evenly dispersed

III. Industrial and consumer considerations

A. Advantages
- Weight saving of material represent an economic saving of importance to the manufacturer
- The over-all cost of producing an article is 40% less by the thermofusion of polyethylene powders than it is by other mechanical molding techniques. The lower cost can be passed on to the consumer.

B. Disadvantages
- Uniform wall thickness is difficult to control
- Inside surfaces may be uneven

IV. Implications for industrial arts

- Products can be made in the shop in the same way they are made in industry
- Practical shop made projects include large sheets to be used for tray bases, using cookie sheets as mold, protective coatings and mounting for plaques, coasters for tumblers and tote boxes
- Materials and equipment are inexpensive

SUMMARY:

Thermofusion of plastic materials in powdered or pellet form is especially well suited for the industrial arts laboratory as it combines many materials that are basic to plastic work. Their use can be both pleasing and functional, as in decorative room dividers.

QUESTIONS:

Q: Why should molds used for thermofusion be free of blemishes?
Q: How may color be added to a project?
Q: Why is it necessary to carefully select materials to be embedded?
Q: What materials can be used for molds for thermofusion?

UNIT IX VINYL DISPERSION - THERMOFUSION

Lesson 43

Demonstration: Rotational molding

OBJECTIVES:

. To demonstrate the process of rotational molding

. To acquaint students with applications of this process in industry

REFERENCES:

1.	Johnson, Dale	"Materials in Designing" Engineering Magazine	Feb. 1963
2.	Johnson, Ira	"Rotational Molding" IAVE Vol. 52, Dec. 1963	pp. 31-33
3.	Zimmerman and Johnson	"Molding Powdered Polyethylene" Modern Plastics Encyclopedia-1963	pp. 717-720
4.	SPI	Plastics Engineering Handbook	p. 275

FOR DISCUSSION:

. Need for a low cost molding process
. Other applications of materials that are used in this process

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Make up a display board of several samples of products made by rotational molding.
. Make up a wall chart on the different types of molding processes.
. Make up give-away projects to promote interest in industrial arts.

BRIEF DESCRIPTION OF PROCESS:

Rotational molding or casting is a method of molding a hollow plastic product which is completely enclosed. The molding compound can be a liquid or a powder. The rotating device must be mounted so that it will permit the mold to revolve in two directions simultaneously in order to provide even distribution and heating.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. An electric oven
. Several casting molds
. Bi-directional rotating device
. A plastisol or organosol vinyl dispersion
. Polyethylene molding powder

LESSON OUTLINE:

I. Selection of the mold

A. The design of the mold may vary but should have a parting line and locking clamps
B. Avoid intricate cavities and large undercuts
C. A cast or spun aluminum mold

II. Preparation of the mold

A. Make sure both halves of the mold are clean
B. Spray mold with a high temperature type of mold release (silicone)

III. Molding

A. Fill mold half full. The wall thickness of the end product depends on the amount of material placed in the mold
B. Place upper half of mold on top of bottom half of mold
C. Lock clamping devices
D. Insert mold into rotating device

IV. Curing

A. Preheat the oven to proper temperature (about 350° F)
B. Slide rotating device into position in oven and start the rotation at a rate of from 5-15 RPM
C. Start timing at this point
D. Make sure no part on the mold will get closer to the heating element than another
E. Heat for approximately 5-8 minutes keeping rotation at an even rate

V. After curing

A. Turn off oven
B. Remove rotating device from oven, using gloves
C. Let mold cool in air for best results
D. If a faster cooling of the mold is desired, immerse in cold water
E. Unclamp the mold and remove the part

VI. Molding with vinyl dispersions

A. Use same steps as above with the noted exceptions
- Instead of using powdered polyethylene, use a vinyl plastisol or organosol
- Time of curing may vary with vinyl dispersions

SUMMARY:

Rotational molding is a process requiring special equipment for making hollow molded parts. It finds its major industrial application in the production of large hollow products in limited production runs.

QUESTIONS:

Q: Why is rotational molding an important process in the plastics industry?
Q: List 2 different materials which will work well with the rotational molding process?
Q: What determines the size of the mold in rotational molding?
Q: Why, in rotational molding, does the mold have to be in two pieces and not just one?
Q: What conditions determine wall thickness of the part in rotational molding?

6.	SPI	Plastics Engineering Handbook	

FOR DISCUSSION:

- The shop use of dye colorants
- Correlation between decorating processes and coating processes

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

- Make a tumbler drum for dry coloring of plastics.
- Produce a fiberglass layup with material imbedded in outside layer.

BRIEF DESCRIPTION OF PROCESS:

The coloring, decorating, and finishing of plastics require methods, materials, and equipment designed specifically for the given case. The entire purpose of decorating or coloring is a more appealing end product. Colorants are in either dry or paste forms. Decorating materials run a wide range of types. Finishing materials have traits of their own, such as wheel speeds, at which they may best be used, abrasiveness, etc. For each type of plastic the manufacutrers have recommended methods of coloring, decorating, and finishing which should be followed.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

- Paste dyes, and dry powder dyes
- Simple drum tumbler and plastic beads. (Tin can with cover will do.)
- Buffing wheel and tape measure
- Inlay of plaid material in surface of fiberglass dish (optional)
- Chart with methods of coloring various types of plastics materials available in school shop

LESSON OUTLINE:

I. Coloring

A. Definition of colorant. A physical substance which modifies light waves striking it by absorbing some and reflecting others, thereby changing light energy composition. This altered light produces the effect called color.

B. Three types of colorants
- Dyes
  a. Chemical makeup
     1. Synthetic
     2. Natural organic
  b. Characteristics
     1. Good color strength
     2. Wide range of colors
     3. Poor resistance to heat
     4. Pronounced tendency to bleed or come to surface of plastic
- Organic pigments (divided into two classes called toners)
  a. Insoluble organic toners (usually salt free)
  b. Lake toners (quite pure, water insoluble, heavy metallic salts)
- Inorganic pigments (generally metallic oxides)
  a. Characteristics
     1. Weather resistant
     2. Heat and light stability
     3. Used in strong concentrations
  b. Miscellaneous group of inorganic pigments for special effects
     1. Metallic (powder)
     2. Pearlescent (flakes)
     3. Fluorescent (powder)
     4. Phosphorescent pigments
     5. Metallic flakes
     6. Color speckles

C. Methods of mixing
- Tumbler for dry powder dyes
- Vat and roller mixing for soluble dyes and colors
- Spray mixing in air before coating product in use of urethane foam

II. Types of processes for decorating

A. Inlay - for example, a print cloth under a clear polyester coating on tray

B. Printing - as seen on shampoo squeeze tubes, key tags, automobile decorations, etc.
- Silk screening
- Offset
- Gravure printing
- Letterpress
- Flexographic
- Photosensitive emulsion
- Hot stamping

C. Through the use of spray, roller, brush - Sample: soap bottle (spray)

D. Adhesion - the decorative labels on products

E. Plating; electro and vacuum metallizing - car dash parts

F. Calendering, embossing - textured vinyl fabric

G. Engraving - desk plates

H. Decalcomania - dinner ware

III. Finishing processes

A. Filing, sanding, buffing, polishing, and cutting

B. Air blasting and etching

C. Tumbling part against part (deflashing or with an abrasive)

D. Airless blast tumbling (deflashing)

E. Chemical solvent uses acetone, etc., to form a coating on surface

F. Flame polishing

SUMMARY:

Most basic plastics processes for fabrication have a finishing sequence, often called a secondary operation. Colorants are generally applied or infused during the fabrication of the article. The decorative materials and processes generally refer to coatings put on after the item is fabricated. The finishing processes are for surface clarity, texture, or the necessary cleaning after fabrication.

QUESTIONS:

Q: Describe five sample plastic products with decorative finishes and tell the decorative process for each product.

Q: When a plastics product is finished by the tumbling method, what is the abrasive used in the process?

Q: How does the chemical solvent affect the surface of a plastic product when it is used as a finishing solvent?

Q: What is the purpose of decorating a plastic product?

PROCESSING CONDITIONS AND SUITABLE COLORANTS FOR USE WITH VARIOUS COMMERCIAL PLASTICS

Plastic	Processing conditions and properties	Colorants
1 Phenol-formaldehyde molded laminates	Mildly alkaline reducing atmosphere Molding temperatures up to 170° C. Usually only moderate light fastness	Spirit and hydrocarbon soluble dyes Spirit soluble acid dyes Lakes and toners Organic pigments Inorganic pigments
2 Phenol-formaldehyde surface coatings and cast	Mildly acidic or mildly alkaline reducing atmospheres Long heating at moderate temperatures Better light fastness than for molded items	Spirit and hydrocarbon soluble dyes Spirit soluble acid dyes Phthalocyanines Lakes and toners Organic pigments Inorganic pigments
3 Urea and melamine-formaldehyde products	Mildly acidic reducing atmosphere for a short period Superlative light fastness	Selected water soluble dyes Inorganic pigments Vat dye pigments Phthalocyanine pigments Organic pigments, lakes, and toners
4 Casein products	Low mixing and extruding temperatures (approximately 100° C.) Acidic reducing conditions during formulation Moderate-good light fastness Must not bleed into the formulating solution	Water soluble acid and direct dyes Organic pigments, toners, and lakes Phthalocyanine pigments Inorganic pigments
5 Cellulose plastics (cellulose acetate, cellulose acetate butyrate, ethyl cellulose, etc.)	Substantially neutral to mildly acidic atmosphere Mixing time on the order of 15 min. at 180° C. Short-time high injection temperature at 180 to 200° C. Moderate-good light fastness	Spirit and hydrocarbon soluble dyes Organic pigments (except those prone to bloom) Lakes and toners Dispersed dyes Basic dyes
6 Polyvinyl chloride and copolymers	Tends to become acidic during processing High temperature compounding up to 170° C. for long periods Very good light fastness High degree of dispersibility	Selected spirit and hydrocarbon soluble Vat dye pigments Organic pigments Inorganic pigments (except those prone to bloom and migrate) Lakes and toners Phthalocyanine pigments
7 Fluorocarbons	High heat stability Resistant to acids and alkalies High degree of dispersibility (very fine)	Inorganic pigments Phthalocyanines and selected organic pigments
8 Polyethylene	Neutral inert processing conditions High temperature processing and extruding depending on grade Very good fastness to light	Organic pigments (except those prone to bloom and migrate) Lakes Vat dye pigments Phthalocyanine pigments Selected hydrocarbon soluble dyes
9 High-density polyethylene	Neutral inert processing conditions Very high temperature processing conditions Very good light fastness and heat stability	Inorganic pigments Organic pigments Phthalocyanine pigments
10 Polymethyl methacrylate	Strongly oxidizing atmosphere during polymerization Moderate temperatures Very good light fastness	Selected hydrocarbon soluble dyes Selected vat dye and organic pigments Phthalocyanine pigments
11 Polyesters	Strongly oxidizing atmosphere during polymerization Very good light fastness High degree of dispersibility	Vat and other organic and inorganic pigments as flushed pastes Inorganic pigments Selected hydrocarbon soluble dyes as flushed pastes
12 Polyurethane foams	Inertness of colorant to catalytic effect and alkaline conditions Light fastness not of importance High degree of dispersibility	Water pulps and flushed pastes of inorganic and organic pigments Vat dye pigments Phthalocyanine pigments
13 Nylon	High heat stability Very good light fastness High degree of dispersibility Strong reducing action of nylon above 500° F.	Inorganic pigments Phthalocyanine pigments Selected anthraquinone pigments
14 Alkyds	Very good light fastness High degree of dispersibility Moderate temperature Bleed resistance	Selected vat dye and thioindigoid pigments Inorganic pigments Phthalocyanine pigments
15 Epoxies	Very good light fastness High dispersibility Moderately high temperature	Organic pigments Phthalocyanine pigments Inorganic pigments
16 Polystyrene	Processing conditions neutral but residual oxidizing catalyst may be present. High temperature processing and injection at 200° C. and above; good to excellent light fastness; high degree of dispersibility	Hydrocarbon soluble dyes Organic pigments Lakes Phthalocyanine pigments Inorganic pigments
17 Polypropylene	Neutral inert processing conditions Very high temperature Very good light fastness and heat stability	Inorganic pigments Organic pigments Phthalocyanine pigments
18 Silicones	Neutral inert processing conditions Molding temperature at 500° F. and above Excellent light fastness and heat stability	Inorganic pigments

UNIT X DECORATING

Lesson 45

Demonstration: Hot foil stamping

OBJECTIVES:

. To develop an understanding of the hot stamping process on plastics

. To show a method of applying a decorative foil surface to plastics

REFERENCES:

1. Coating Products — Literature on Films
   101 W. Forest Avenue
   Englewood, New Jersey

2. The Kingsley Machine Co. "Plastic Marking Machine" — Equipment Literature
   Hollywood, Calif.

FOR DISCUSSION:

. The industrial application of hot foil stamping on plastics
. The commercial potential in a home workshop

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Make key chain identification tag with students name.
. Experiment with different plastics.
. Produce name badges.

BRIEF DESCRIPTION OF PROCESS:

Hot foil stamping is a method of decorating plastic materials. Heated metal dies are pressed on to a plastic foil and against the object to be stamped. The color on the foil releases and adheres to the plastic.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Hot stamping machine
. Plastic item to be stamped (suggest a flat sheet item)
. Die, type, or other form for desired decoration (suggest standard type supplied with machine)
. Foil suitable for the plastic used (See foil literature for correct type(s).)

LESSON OUTLINE:

I. Description of hot stamping on plastics

   A. Die localizes heat and pressure on foil
   B. Plastic foil and material is heated under pressure
   C. The coating of foil heat-seals itself to the area of contact

II. Equipment, setup, and operation

   A. Press operation
      - Set up type, assemble die, etc.
      - Place in press and preheat
      - Install foil, printable side down, facing item; test sample impression on scrap plastic (same as item)

B. Item preparation and press run
- Clean surface of item carefully, using rag
- Insert in press in proper register with die
- Hot stamp the item(s)
- Turn off press and label "HOT"

III. Area clean up and safety

A. Remove type or die, using gloves
B. Allow to cool
C. Redistribute type or store die

SUMMARY:

When using a foil to hot stamp on plastics attention should be paid to five variables. The pressure applied to the foil, the type of foil used, the plastic used and the length of the cycle time will all effect the result produced. The size and type of die used is basically a problem of heat distribution.

The finished hot-stamped item has an attractive surface or detail. Color is varied according to the foil used and allows for a detailed metal-like appearance.

QUESTIONS:

Q: What are the purposes of hot stamping on plastics?
Q: What are the variables in hot stamping?

ICS 230

UNIT X DECORATING

Lesson 46

Related Lesson: Machine engraving

OBJECTIVES:

. To acquaint the student with the machine engraving process

. To develop in the student an understanding of materials and equipment used in machine engraving of plastics

REFERENCES:

1.	Cherry, Raymond	General Plastics 1964 Revised	Chap. 29
2.	Edwards, Lauton	Industrial Arts Plastics	pp. 98-104

FOR DISCUSSION:

. Commercial use of machine engraving
. Types of plastic materials used
. Methods of machine engraving plastics

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Produce name plates and plaques.
. Experiment with different fillers when solid stock is engraved.

BRIEF DESCRIPTION OF PROCESS:

Machine engraving is one process of incising lines or designs in the surface of a plastic. The machine used is an accurate pantograph using a stylus following a line in a die to guide the rotary cutter engraving the plastic.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

. Pantograph (wood type) Definition: An instrument for copying a diagram to any predetermined scale. The pantograph consists of four light, rigid bars joined in the form of a parallelogram.
. Laminated blocks
. Products made by the engraving process - house numbers, name plates, desk signs, etc.

LESSON OUTLINE:

I. Other engraving processes

A. Earliest scratching on stone caves a forerunner of engraving

B. Highly developed hand skill used to engrave or cut away thin line of metal

C. Wood engraving used for early block printing

D. Machine process used on many materials. Used on plastics in the 1940's

II. Application

A. Commercial use: Signs, name plates
- Hospitals - x-ray room
- Hotels - check out time signs
- Banks - loan department signs
- Home and school - desk name plates, etc.

B. Industrial use
- Instruction plates and numbers
- Instrument panels and dials

III. Machines used for process (for flat, and 3 dimension stock)

A. Built around the use of the pantograph
- They reduce from master type to work
- For plastics the ratio range is 2:1 to 7:1

B. Power for cutting
- Electric motors run on 115V and produce 1/6 to 1/4 HP
- Speeds should be variable from 1200 - 3400 RPM

C. Cutting tool material
- High speed steel is the most common
- Tungsten carbide is also frequently used
- The tools are sometimes diamond tipped

D. Tracing stylus (follows master type in operation)
- Hardened steel is frequently used
- The stylus is often carbide tipped

E. Copy tables, to hold material to be traced, type or design

F. Work table, holds blank to be engraved

G. Depth control
- It is most commonly mechanical
- Pneumatic control used in some instances

H. Size of machine (varies with master type to be used. (Master type 1/16" - 7")

I. Cost of machines used for engraving plastics varies from $95 to $12,000

IV. Master type or copy

A. Standard
- Flat bottom grooved
- Vee grooved

B. Reverse lettering (used for transparent and translucent materials)

C. Two or three dimensional material may be used

D. Made usually from brass

E. Cost depends on style type used and size - relatively expensive for most copy

CES 232

V. Materials used for engraving

A. Laminated phenolics
- Surface 1/16, 1/8, 3/32 thick
- Engraving through top layer exposes core
- Colors
  a. Core - black, white, red
  b. Surface - many colors and designs, including wood grain

B. Acrylics
- Solid stock generally used with reverse type
- Colored, clear, opaque, and translucent

C. Other materials by trade name
- Gravoply - pliable
- Gravoflex - flexible
- Micro laminated stock
- Green laminated stock
- Formica, panelyte

VI. Basic methods of machine engraving

A. When using laminated material the top layer is cut through, resulting in permanent lettering on a contrasting background

B. When using solid opaque stock the engraved area is filled with wax crayon or other fillers such as paint or lacquer of contrasting color

C. When using solid transparent or translucent materials engraved on the reverse side, a reverse master type is used. The engraved area may be colored as in use of opaque solid stock.

VII. Consumer value

A. Wax filled engravings are less expensive than laminated stock. The quality of the engraving depends on the machines and the materials used.

VIII. Guidance

A. Small business opportunity

B. Custom shops, small job shops

SUMMARY:

In machine engraving, the size and type of machine, the plastic material, and the master copy may vary considerably. The quality of the end product depends largely upon the proper selection of the materials and master copy for the particular product desired.

QUESTIONS:

Q: What are some commercial uses of machine engraved plastics?
Q: What is the mechanical principle that engraving machines are based on?
Q: What are two types of plastics used in engraving?
Q: What are two methods of making engraved name plates on an engraving machine?

SES 233

UNIT X DECORATING

Lesson 47

Demonstration: Machine engraving

OBJECTIVES:

- To show students the process of machine engraving of plastics
- To develop in the student an understanding of the pantograph machine to be used
- To develop in the student an appreciation of the materials used for machine engraving

REFERENCES:

1.	Cherry, Raymond	General Plastics 1964 Revision	Ch. 29
2.	Edwards, Lauton	Industrial Arts Plastics	pp. 100-104

FOR DISCUSSION:

- Extensive use of machine engraving for metal
- Differences in machines used
- Differences in cutting tools used

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

- Produce name tags, desk name plates, plaques.
- Make high pressure plastic laminates (similar to formica) on compression press, and engrave a name plate or similar item.

BRIEF DESCRIPTION OF PROCESS:

Machine engraving uses a rotary cutter guided by a stylus in a template. The cutter and stylus are connected by a precision-type pantograph machine.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

- Engraving machine - trade names: Mico, H. D. Preis, Green Inc., Hermes
- Master type or templates - letters, numbers etc.
- Plastic engraving stock - laminated, solid
- Fill material - wax crayon, paint, or lacquer

LESSON OUTLINE:

I. Material used

A. Laminated phenolics
B. Solid stock (acrylic), colored or clear

II. Engraving process

A. Select letters or numbers (standard or reversed type)
B. Place master type in template on holding table
C. Center copy material in template
D. Open work vise on work table
E. Insert work to be engraved
F. Set pantograph arms for required reduction
G. Locate cutter in correct position, holding stylus on first letter
H. Turn motor on and adjust to correct speed

I. Follow letter patterns with stylus using three fingers of right hand to guide stylus. (Depress cutter handle with left hand.)
J. Complete engraving by following each letter or number
K. Bevel edges as desired
L. Turn off machine and remove engraved material
M. Fill engraved surface if laminated stock is not used

V. Industrial considerations

A. Advantages
- Process offers ease in setup of machine for short runs
- Precision machine produces an accurate detailed copy
- Plastic material is easily obtained

B. Disadvantages
- The process is not practical for long run jobs
- Cost of type and other copy material is high

SUMMARY:

To make an article on the engraving machine you must first select the master type and blank material to be used. The pantograph arms of the machine should then be adjusted to provide the proper ratio of master copy to the piece to be engraved. If care is taken during the engraving process, no additional surface finishing of the article is necessary.

QUESTIONS:

Q: How are different ratios of copy-to-work obtained with the use of the engraving machine?
Q: What type of motor is used for powering an engraving machine?
Q: From what type of steel are the engraving cutting tools made?

UNIT XI MATERIALS

Lesson 48

Related Lesson: Testing plastics materials

OBJECTIVES:

. To acquaint the student with the main categories of testing

. To acquaint the student with the significance of each type of test

. To convey the importance of testing plastics materials

REFERENCES:

1.	ASTM	Plastic-Methods of Testing	Part 27
2.	Celanese	Standard tests on Plastics	
3.	SPI	Plastics Engineering Hand Book	pp. 541-550
4.	Swanson, Robert	Plastics Technology	pp. 12-31

FOR DISCUSSION:

. What testing signifies for the manufacturers
. Difference between "captive" and independent testing agencies
. The four main categories of testing plastic materials

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Develop testing equipment for plastics laboratory.
. Experiment in testing of different plastics materials.

BRIEF DESCRIPTION OF PROCESS:

The testing of the physical properties of items made of plastics is of paramount importance to manufacturers today. The purpose of such tests may be for quality control in production, as a check by the purchaser to see if the item meets specifications, or for the establishment of data for engineering and design. These tests fall into four main categories: mechanical properties; permanence properties; thermal properties; and flamability tests. Each of these four tests employs different means of checking a plastics material to see if it is the proper material to do the job.

MATERIALS, EQUIPMENT AND/OR TEACHING AIDS:

A chart listing the five main categories and subdivisions of tests.

LESSON OUTLINE:

I. Mechanical tests (Basic reference #3 pp. 541-44)

A. Purposes of mechanical tests
- Crushing tests are designed to check whether or not the article will stand up to compressional stresses that it may encounter when in customer service
- Wear tests are designed to find out how long an item made of plastic will withstand the usage to which it is subjected while in consumer use
- Fatigue tests are set up to check whether or not the item will fail after repeated loading to a stress less than its short time ultimate strength

ECS 237

B. Strength. (Testing molded articles for physical properties)

- Falling weight test. This test is made by dropping an object of a given weight and dimension from a predetermined height on a specimen and examining the effect of the impact.

Impact Testing
courtesy of Celanese Plastics Company

- Pendulum test (IZOD). The sample is clamped in a pendulum testing machine, and the pendulum is released so that it strikes the sample. The force required by the pendulum to break the sample is calibrated by the height which the pendulum reaches on the follow through.

- Tumbling impact test. Items of a known molded material are placed in a tumbling machine with the same amount of an unknown molded material. The items are tumbled for a specific length of time and then removed and inspected. The items made of the weaker molded material will show the greater amount of wear.

- Projectile impact test. A projectile is fired from a gas pressurized gun, and the impact strength of the specimen is calculated from the speeds of the projectile before and after impact as measured by photocells in circuit with electrical timing devices.

- Tensile strength. Tensile properties are the most important single indication of strength in a material. The force needed to pull the specimen apart is determined as well as how much the material stretches before breaking.

Tensile Testing Machine
courtesy of Celanese Plastics Company

TENSILE TEST SPECIMEN

CC238

- Compressive strength. The compressive strength of material is determined as a pressure measured in pounds per square inch required to rupture the specimen or deform the specimen a given percentage of its height. It may be rated as PSI at rupture, or at a given percentage of yield.

Compression Testing
courtesy of Celanese Plastics Company

II. Permanence properties tests

A. Dimensional stability tests are designed to find out whether there are any changes in dimensions due to any of the following factors:
- A deformation under load known as cold flow
- Swelling or shrinking owing to absorption of moisture or drying
- Aging effects owing to cycles of absorption of moisture and drying
- Internal stress
- Change in temperature

B. Weathering tests. These arrive at an evaluation of the resistance of materials to outdoor exposure which may cause degradation, loss of original beauty, and, in some cases, complete erosion. This is generally accomplished by one of the following means:
- Weathering rack (sun, rain, snow, heat, cold, industrial acids in the air)
- Accelerated weathering machines (speed up weathering through artificial means)

C. Effects of radiation test. This is a check to see whether radiation causes any damage, or whether it may, in some cases, be beneficial.

D. Moisture resistance test. This involves a check of the physical properties directly influenced by the moisture content of plastics, such as electrical resistance, dielectric losses, mechanical strength, appearance and dimensions.

E. Chemical resistance. This test is necessary only when the item is to come into contact with water and solvents which may cause a chemical reaction.

F. Effects of molded stress. This is testing designed as a check on the possibility of dimensional changes caused by any of the following factors:
- Misalignment of molecules
- Packing stress caused by forcing unplasticized material into the mold
- Non-uniform cooling in the mold
- Quick heat or cold, or local overheating during machining or finishing

239

III. Thermal property tests (Effect of temperature). These involve checking materials to see how they have been affected by heat and cold.

IV. Burning test

A. Heat is applied to a specimen, and if it does not burn, it will be classed "non-burning."

B. If it burns for four inches, it will be classified as "burning" by this test

C. If the flame goes out before it reaches four inches, the specimen is classified "self-extinguishing."

D. The length that it did burn is reported as the "extent of burning."

V. Specific gravity test. A piece of material is held by a fine piece of wire, weighed in air, and then submerged in water. While it is in water, it is weighed again. From the weight difference, the density is calculated. Specific gravity is the ratio of a given volume of material at 73.4°F to that of an equal volume of water at the same temperature. Density is the weight per unit volume of material at 73.4°F.

SUMMARY:

Many of these methods originated in the technology of metals; however, there is little doubt that future testing of articles made from plastics will depend on modifications of existing techniques or on new concepts arising from the unique needs of organic materials.

QUESTIONS:

Q: What are the four main categories of tests for plastics?
Q: Define each of the four main categories of tests for plastics.
Q: What two methods are used for weathering tests?

241
OPS

BRIEF DESCRIPTION OF PROCESS:

Plastics are man-made materials. They may be any one of a large and varied group of materials consisting wholly or in part of combinations of carbon with oxygen, hydrogen, nitrogen and other organic and inorganic elements.

Plastics are solid in the finished state but at some stage in their manufacture they are made liquid and capable of being formed into various shapes. The application of heat or pressure or both usually causes the change of state.

MATERIALS, EQUIPMENT, AND/OR TEACHING AIDS:

. Samples of thermoset and thermoplastic products
. Samples of plastic pellets, sheet stock, and beads
. Wall charts
. Models indicating basic molecular structures

LESSON OUTLINE:

I. Historical origins and commercial background

A. Romans and Egyptians collected secretions of lac bug to form shellac sheets

B. Commercial development
- John Hyatt - cellulose 1868
- Leo Baekeland - phenolic (Bakelite) 1909

II. Four families of plastics

A. Natural - shellac, copal, resin, and pitch

B. Cellulose - treated cotton or pulpwood

C. Protein - soybean meal and the casein of milk

D. Synthetic - product built by using organic chemical building blocks, called atoms and molecules, starting from raw materials such as coal, petroleum, air, water

III. Branches of Chemistry

A. Inorganic chemistry. This is a branch of chemical science that deals with non carbon molecules.

B. Organic. This is a branch of chemical science that deals with the hundreds of thousands of known chemical molecules containing a large percentage of the element carbon in their makeup. Plastics is a branch of organic chemistry.
- Organic substances are large, complex, molecular structures
- In them, the carbon atom combines readily with other carbon atoms as well as atoms of other elements
- Their unstable molecular structure breaks up easily when heated

C. Polymer chemistry. This is a branch of organic chemistry
- The atom is the smallest particle of an element
- The molecule is the smallest portion of an element or compound which retains the chemical identity and properties of the substance mass. It is made up of atoms.

GAS 242

- A monomer (Mono - single, Mer - part) is a one part, single molecular unit. Basic building blocks (molecules) joined end to end form polymers.

- A polymer (Poly - many, Mer - part) is a giant molecule made up of many parts (single molecules)
- Polymerization is the act of combining two or more molecules of a monomer into a single large molecule, thus creating a different substance called a polymer

- A catalyst is a chemical substance which is used in assisting chemical reactions without combining chemically itself
  . It is sometimes used to speed up or start a reaction
  . It is at other times used to stop a reaction (inhibitor)

IV. Thermoplastics

A. The plastics of this group soften when heated. Molecules are thus loosened so that they may move freely.
B. They have a long chain-like molecular structure
C. They can be re-shaped
D. Examples - polystyrene, polyethylene, polypropylene, nylon

V. Thermoset plastics

A. The plastics in this group have a cage-like molecular structure
B. They are heated and formed permanently
C. Examples - melamine, polyesters, phenolics, ureas, epoxies

Molecular Arrangements for Thermosetting Plastics and for Thermoplastics
courtesy of The Lionel Corporation

SUMMARY:

All plastics are giant-molecule, high molecular weight materials. The broad field of study that has contributed the varied plastics materials is called organic chemistry. The number of monomers in a giant chain-like molecule and the nature of their arrangement in the plastic are important determinants of the physical and chemical properties of the plastic, which in turn determines the thermoset or thermoplastic qualities of the material.

QUESTIONS:

Q: What function does the catalyst fulfill when mixed with a polyester resin?

Q: How does the study of organic chemistry differ from the study of inorganic chemistry?

Q: Are plastics considered synthetic materials?

Q: Use two sketches to compare the molecular structure of thermoplastics and thermoset plastics.

UNIT XII

GUIDANCE

Lesson Page

50 Occupational Opportunities in Plastics (related) 178

UNIT XII GUIDANCE

Lesson 50

Related Lesson: Occupational opportunities in plastics

OBJECTIVES:

. To acquaint the student with possible employment opportunities in the plastics field

. To develop in the student an understanding of the education and training needed to qualify for employment in the plastics field

REFERENCES:

1. Dearle, Denis A.	Opportunities in Plastic-Careers Occupational Outlook	Total Content
2. *United States Dept. of Labor	Occupational Outlook Handbook (1961)

4. *State of N. Y. Dept. of Commerce	Industrial Directory of New York (1958)	
5. McGraw-Hill, Inc.	Modern Plastics Magazine	General

FOR DISCUSSION:

. Safety Hazards and Working Conditions
. Education and Training
. Interrelationships of occupations

EXPERIMENTAL AND/OR PROJECT ACTIVITIES:

. Investigate the specific duties of a setup man in an injection molding plant.
. Determine which high school courses should be taken to prepare for a chemical engineering career in plastics.
. Make an occupational analysis of one occupation in the plastics industry.

LESSON OUTLINE:

The plastics industry is expected to provide thousands of job opportunities for new workers during the late 1960's and the 1970's. The industry's work force is expected to increase at a faster rate than the nation's total labor force.

I. General employment outlook

A. Growth in number of workers through 1961 (Ref. 3)
- The number rose from 18,000 in 1940 to 86,000 in 1956 and to 152,000 in 1961
- The growth of the labor force is expected to continue at a faster rate than the increase of manufacturers in general
- Technical improvement has raised output per worker
- Improved materials and exploration in new fields has kept employment up

B. Distribution of workers as of 1961 (Ref. 2)
- Of the 152,000 workers, 103,000 were production workers
- Approximately 40 percent of the total number of workers were unspecialized
- About 25 percent were semi-skilled (largely machine operators)
- The number of skilled craftsmen and foremen comprised approximately 10 percent of total. (One-half of these workers were tool and die makers.)
- Professional and technical workers made up the remaining 25 percent of the workers. Because of a large number of small industries (50 workers or less) many of these professional workers were proprietors and managers.

II. Wage Considerations

A. Vary in accordance with particular job performed. The salaries are paid in proportion to the responsibilities involved and the training necessary to carry out these responsibilities.

B. Earnings of production workers (molders, setup men, inspectors, etc.) as of 1961
- Average work week was 41.6 hours
- Average rate of pay was $2.59
- Weekly wage average was $107.74
- Females made up one third of the labor force

C. Salaried employees earnings (molding material salesmen, plant production managers, cost estimators, product designers and engineers)
- Salaries range from $4,200 to $9,000 and sometimes beyond
- Increases are based entirely on merit and the ability of the individual to show results in his particular job

III. Working Conditions (Ref. 1)

A. Shift work. (Most large plants work around the clock.)
- Usually 3 shifts are in force
- 5 cents extra per hour paid for second shift.
- 10 cents extra paid for third shift

B. Vacations
- 1-week vacation granted with pay after one year
- 2-weeks paid after 5 years
- 3-weeks paid after 15-20 years

C. Other Benefits
- Life insurance
- Health and hospitalization
- Pensions

D. Physical conditions
- They are good compared with factory work in general
- Buildings are generally well lighted and adequately ventilated
- Noise and heat may prove to be a problem
- Odors and gases may cause health problems for some persons

IV. Education and Training (Ref. 2)

A. Unskilled and semi-skilled labor (molders, finishers, inspectors, set-up men, etc.)
- Training
  a. General practice is to hire inexperienced persons and train them on the job
  b. Training period varies with job. (Ranges from 3 days to several months or more.)
- Education. A high school education is preferred, but not always required.
- Extra education and training usually needed for advancement

B. Skilled Workers
- Tool and die makers and machinists generally serve an apprenticeship of 4-5 years, or attend trade school and shorter apprenticeship
  a. They work with experienced craftsmen
  b. They attend classes for instruction in related subjects
- Maintenance men generally learn from experienced craftsmen as helpers
- High school or vocational school education is necessary
- Tests for mechanical and mathematical aptitudes are sometimes given

C. Professional workers (engineers, mechanical, chemical, and sales engineers, technicans, cost estimators, etc.)
- College degree in chemistry, engineering, or special field is required for most professional and technical jobs
- Salesmen are also required to have some technical training to understand the nature of the product
- Technicians. 2 year technical degrees or graduation from community colleges is usually acceptable.

D. For information concerning schools of higher education in the plastics field, refer to (Ref. 1-pp. 140, 141, 31-32)

V. Plant Location (Refer to map)

A. New England area has largest number of plastics concerns
B. Metropolitan New York and parts of New Jersey have high concentration
C. Chicago and midwest area are next in industrial concentration
D. Ohio and California more recently have become sections with increased plastics activity commercially

VI. Future of the Industry (Ref. 1)

A. Barometer for future may be found in the rapid rise in resin production
- In 1950, 2 billion pounds of resin were produced
- In 1961, 6 1/2 billion pounds of resin were produced
- In 1964, nearly 10 billion pounds of resin were produced

B. Sales increased from 14 million dollars to almost 400 million dollars between 1946 and 1961. Many new products introduced.

C. Highly automated industry, so there is an expanding need for technically competent workers

D. Industry estimates that only 3 percent of potential market has been realized in 1963

SUMMARY:

The plastics industry is still a rapidly growing industry. Although the rate of employment is not expected to increase at the same rate as production, employment should increase at a steady rate as new markets and new materials are discovered.

Most of the new job openings will be for inexperienced persons who can be trained for production jobs, but there will be many openings for engineering, sales, and other technical and professional personnel.

QUESTIONS:

Q: Approximately how many workers were employed in the plastics industry in 1961?

Q: What are some of the semi-skilled jobs in the plastics industry?

Q: What type of education is necessary to become an engineer in the plastics industry?

Q: What are the future prospects for employment in the plastics industry?

APPENDIX

Seventh Year Outline. 184

251

Seventh Year Outline

Plastics Area in General Industrial Arts

	Lesson	Unit	Content	Time
1	Injection Molding	II	Basic instruction related to heat, pressure and cycling time for process	15 min.
2	Compression Molding	II	Understanding scope of process application including variety of resins, filler materials, heat and pressure considerations	15 min.
3	Thermoforming	II	Blow forming, vacuum forming, mold design relationships, effect of heat and pressure on one or two common materials	15 min.
4	Mold Making	III	Simple hydrocal mold production and thermo-forming activity	30 min.
5	Bonding	IV	Cementing, heat sealing, and welding (optional)	20 min.
6	Laminating	V	Reinforced fiberglass	15 min.
7	Laminating	V	Low pressure and high pressure including biological specimens 2-dimensional and production of Formica type material	15 min.
8	Encapsulation	VI	Embedding 3-dimensional electronic, biological or other specimens in-cluding coins	15 min.
9	Foams	VII	Polystyrene bead expansion, rigid and flexible resin foams expansion	10-20 min.
10	Coating	VIII	Cold dip and fluidized bed - materials, application, technique	10 min.
11	Vinyl Dispersion and/or Rotational Molding	IX	Simple dip technique with organosols or plastisols	10 min.

A great deal of pupil project and/or experimental activity can be combined with woodworking and ceramics. For example: moldmaking which requires wooden flasks and gypsum casting.

Check your local area for plastics companies and record the name of the person to contact in this space.

Suggested Equipment List for Plastics

24 Students

Junior and/or Senior High School

No.	Description	Cost
(2)	1/5 ounce or larger Injection Molding machines, Simplomatic PL-63 or equal - Jr. and Sr. High Sources: 5, 7, 22, 32, 38 @$300.00 *	$600.00
(4)	Mold blanks for above Injection Molder - Jr. and Sr. Sources: 5, 7, 22, 32, 38 @$10.00	40.00
(1)	12 ton or larger capacity, Compression/Laminating Press complete with heated and cooled platens, facing sheets for laminating, thermometers and 1 compression mold, etc. Carver Model 150 or Pasadena Hydraulics Labmaster or equal - Jr. and Sr. Sources: 5, 8, 12, 35a, 44	550.00
(1)	Vacuum former 7" x 7" with vacuum source and heating unit, Iasco 7" x 7" or equal - Jr. High Source: 24	80.00
(1)	Vacuum former 10" x 14" with vacuum source and heating unit, Orbit Model SA-2500 or equal - Jr. High Sources: 4, 5, 10, 24, 43	145.00
(1)	Portable Scrap Granulator 7" x 6 1/2" throat or larger capacity with 1 Hp motor and switch, Injection Molders Supply Co. Model M-1 or equal - Sr. High Source: 26	450.00
(1)	Vacuum, pressure and mechanical former 18" x 18" with heating unit, material clamping device, vacuum and pressure sources, DIACRO Model 18 with hinged clamp frame or equal - Sr. High Sources: 5, 14	875.00
(1)	Vacuum former, 10" x 14" with vacuum source and heating unit, Orbit Model SA-2500, or equal - Sr. High Sources: 4, 5, 10, 24, 43	145.00
(1)	Electric oven and burner unit, electric kitchen stove with large oven and four surface cooking units, 30" or 40" with wide oven or equal - Jr. and Sr. Source: Local hardware store	325.00
	OR	
(1)	Hot air oven, thermostatically controlled 450° or higher maximum temperature, interior minimum dimensions 26" wide by 20" high x 20" deep - Broadhead-Garrett Model 51-550 or equal - Jr. and Sr. High Sources: 1, 11, 13, 16, 19, 23, 24 AND	383.00
(1)	Electric hot plate, temperature controlled model HP-A8805B, Thermolyne Corporation, Duhugue, Iowa	17.00

* See Optional Equipment, page 192.

No.	Description	Cost
(1)	Strip heater 18" long or longer, Hotpack 18" or equal Sources: 5, 11, 23, 24 - Jr. and Sr.	$ 22.50
(1)	Heat Sealer, hand operated, Caig Lab. Model Ersa #50p, 150p or 50F or equal - Jr. and Sr. Sources: 6, 20, 37, 42, 48	15.00
(1)	Plastics Welding Unit, hand operated, kit with extra tips, etc. Kamweld 15 TM or equal - Jr. and Sr. Sources: 5, 7, 27, 48	105.00
(1)	Glue pot or bucket heater unit for cold dripping Sources: 5, 20 - Jr. and Sr.	25.00
(1)	Engraving machine, Micro Model or equal - Sr. High Sources: 18, 21, 31	150.00
(1)	Hot stamping machine, Kingsley or equal - Sr. High Sources: 2, 28, 30	295.00
(1)	Thermometer, 6" shank, dial face reading type 100°F to 600°F, Weston or equal - Jr. and Sr. Sources: 49	5.00
(1)	Power paint mixing paddle - Jr. and Sr. High Source: Local hardware store	1.00
(2)	Double wheel electric buffer, 6" wheel or larger, 1/2 Hp or larger, 1725 RPM - Sr. High Sources: 5, 11, 24 @$50.00	100.00
	Assorted molds, jello molds, muffin tins, glass tumblers, leaf molds, casting molds - Jr. and Sr. Sources: Local hardware store	25.00
(1)	Pressure cooker, 10 qt. or larger - Jr. and Sr. Source: Local stores	20.00
(3)	Air pressure regulators, 0 to 100 psi, single stage, spray painting type @$30.00 - Jr. and Sr. Sources: Local automotive supply stores etc.	30.00
(1)	Air compressor - capacity at least equal to the air consumption of two air operated injection molders with necessary valves, hose, quick connectors Sources: Local Jr. and Sr.	350.00
(2)	Air line oilers for injection molders - Jr. and Sr. Source: Local @$10.00	20.00
(1)	Postal scales, 2 lbs. capacity, spring type for weighing materials - Jr. and Sr. Source: Local	5.00
(1)	Electroplating unit, 5 amp. capacity or larger power unit and plating equipment and chemical set, Warner 5 amp. power unit #971 x plus plating outfit #3 - Jr. and Sr. Sources: 5, 35b	110.00

OPTIONAL EQUIPMENT

No.	Description	Cost
(1)	Extruder, laboratory type, 3/4" screw or larger - 20:1 screw dia. to screw length ratio - Wayne 3/4" table model or equal Sources: 29, 46	$825.00
(1)	Blow molding attachment for plastics extruder, hand or air operated, mold closure device Source: 29	250.00
(1)	Rotational molding machine, laboratory model Source: 9	1000.00
(1)	Set testing equipment - tests for tensile, compression, shear, transverse, hardness, modulus of elasticity Broadhead-Garrett, Model UTM-2B or equal Sources: 5, 36, 40, 47	1000.00
(1)	All materials spray gun, for spraying plaster, plastic resins and rubber, with extra nozzles, cups, lids and hose, R-2 all materials gun or equal Sources: 35c	80.00
(1)	Portable Plastics School consists of 14 volumes: Each volume contains raw materials and finished product samples held in place by flexible bands for removal and inspection. Multi-colored charts show the method of polymerization starting from the basic raw materials and also the various methods of producing finished articles. The Commentary volume gives a brief history of each material, raw materials production, production of the plastic material, properties, processing methods and applications. Source: 52	137.00
(1)	Honajector, plastic injection molder, Model 101. Including assortment of molds and accessories. Source: 53	325.00
(1)	Injection molder "wasp" Mini-Jector, Model 45 Source: 54	965.00

LIST OF EQUIPMENT MANUFACTURERS AND DISTRIBUTORS

The names of companies with their addresses of the main source of plastics equipment are given here. Complete listings of machine manufacturers can be found in the *Modern Plastics Encyclopedia*.

1. Acme Plastic Machinery
   500 Sawmill River Road
   Yonkers, New York

2. Admiral Coated Products Inc.
   20 Railroad Avenue
   Hackensack, New Jersey

3. American Handicrafts
   384 Fifth Avenue
   New York 1, New York

4. Auto-Vac Co.
   106 Meadow Street
   Fairfield, Conn.

5. Broadhead-Garrett Co.
   4560 East 71st Street
   Cleveland, Ohio

6. Caig Laboratories
   46 Stanwood Road
   New Hyde Park, L. I., N. Y.

7. Canadian Aviation Electronics, Ltd.
   Dept. FG-2 Box 2030 St. Laurent
   Montreal 9, Quebec, Canada

8. Carver, Fred S., Co.
   5 Chatham Road
   Summit, New Jersey

9. Akron Presform Mold Co.
   2038 Main Street
   Cuyahoga Falls, Ohio

10. Comet Industries
    1 N640 York Road
    Bensonville, Illinois 60106

11. Cope Plastics
    Highway 100
    Godfrey, Illinois 62035

12. Dake Corp.
    Grand Haven, Michigan

13. Despatch Oven Co.
    619 S. E. 8th Street
    Minneapolis, Minn.

14. DiAcro Corp.
    Lake City, Michigan

15. Entoleter Inc.
    Box 904
    New Haven, Conn.

16. Fisher Scientific
    633 Greenwich St.
    New York 14, N. Y.

17. Glenn Electric
    Heater Corp.
    Erie, Pennsylvania

18. Green Instrument
    295 Vassar Street
    Cambridge 39, Mass.

19. Grieve-Hendry Co.
    1358 N. Elston Ave.
    Chicago, Illinois

20. Hastings Plastics
    1704 Colorado Avenue
    Santa Monica, Calif.

21. Hermes Engraving Mach.
    154 West 14th Street
    New York, New York

22. Hinchman Mfg. Co., Inc.
    259 E. First Avenue
    Roselle, New Jersey

23. Hot Pack Co.
5083 Cottman Avenue
Philadelphia, Pa.

24. Industrial Arts Supply Co.
3002 Hennepin Avenue
Minneapolis 8, Minn.

25. Industrial Heater Corp.
417 Canal Street
New York 13, New York

26. Injection Molding Supply Co.
17601 South Miles Road
Cleveland 28, Ohio

27. Kamweld Products Co.
932 R Washington Street
Norwood, Massachusetts

28. Kensal-Olsen Mark Inc.
124-132 White Street
New York 13, New York

29. Killion Extruders, Inc.
56 Depot Street
Verona, New Jersey

30. Kingsley Machine Co.
850 Cahuenga
Hollywood, California

31. Micro Instrument Co.
80 Trawbridge Street
Cambridge, Maryland

32. Newbury Industries, Inc.
Newbury, Ohio

33. Ogden Manufacturing Co.
2520 W. Irving Park Rd.
Chicago, Illinois 60618

34. Pacific Plastics Machinery Corp.
228 San Lorenzo Street
Pomona, California

35. (a) Pasadena Hydraulics Inc.
1433 Lidcombe
El Monte, California

35. (b) Paxton/Patterson
45 Samworth Road
Clifton, N. J. 07012

(c) Plaster Supply House
Box No. 551
Chicago 90, Illinois

36. Research Products Co.
P.O. Box 1047
St. Petersburg, Florida 33731

37. Seal Inc.
Shelton, Conn.

38. Simplomatic Manufacturing Co.
4416 W. Chicago Avenue
Chicago 51, Illinois

39. South Bend Lathe
South Bend, Indiana

40. Testing Machines Inc.
72 Jericho Turnpike
Mineola, New York

41. Thermal, Inc.
9408 Robinson Road
Franklin Park, Ill.

42. Vertrod Corp.
2037 Utica Avenue
Brooklyn 34, N. Y.

43. Vac Form
5 North Water Street
South Norwalk, Conn.

44. Wabash Metal Products
1569 Morris Street
Wabash, Indiana

45. Watlow Electric Mfg. Co.
12001 Lockland Road
St. Louis 41, Mo.

46. Wayne Machine and Die
23-B Grand Street
Garfield, New Jersey

47. W. C. Dillon and Co.
14620 Kiswick Street
Van Nuys, Calif.

48. Weldotron Corp.
913 M Felinghuysen Ave.
Newark 14, New Jersey

49. Weston Instrument and
Electronics
Newark 14, New Jersey

50. Wiegand, Edwin L. Co.
7613 Thomas Blvd.
Pittsburgh 8, Pa.

51. Wing and Son Corp.
384 Broadway
Albany 1, New York

52. International Plastics Industry
Consultants, Inc.
P.O. Box 1324
Long Island City 1, New York

53. Nassau Manufacturing Company
923 Old Nepperhan Avenue
Yonkers, New York 10703

54. Newbury Industries, Inc.
Newbury, Ohio

LIST OF SUPPLIES FOR PLASTICS

This list includes most of those materials which are needed for the units in this course of study. Additional materials may be obtained from the suppliers listed here or from local sources. Numbers which appear after each material listed are the code numbers which correspond to the number preceeding each firm listed in the List of Material Suppliers and Distributors on page 198.

Materials	Supplier
A. B. S. sheet	32
acetate	6, 5
acetone	20, 6
acrylic	6, 7
adhesives	15
balls, styrene	11, 28
buffing	15, 20, 4, 7
butyrate peelable resin	18, 25, 10
butyrate powder	13
casting resins, clear polyester	15, 20, 29, 4, 7
catalysts	15, 20
cements	15, 20, 29, 7, 5
cobalt	6
color concentrates	37
colorants	15, 29, 4, 14
chrome plating chemicals	12
Devcon casting resins	5
dyes	20, 29, 7
elastomers, room temp. vulcanizing	15, 16, 1
epoxy resin	29, 5, 7, 34, 6, 31
electric chemicals	12
epoxy cement	20
engraving stock	7

Materials	Supplier
ethylene dichloride	5
fiber glass, cloth mats, roving	20, 29, 7, 6
film, polyethylene	15, 7
films, heat sealing	6
flourescent powders	15
fluidizing powder	10
foams, polyurethane	20, 7
foil, hot stamping	2, 22, 23
glass reinforcement, cloth mat, roving	20, 29, 7, 6
gloves	11
glues	29
gypsum cement	34
lacquers	34
laminating engraving stock	7
latex rubber	20
melamine, molding compound	3, 9, 26, 30
methylene dichloride	20
molecular modules, styrene balls	11, 28
mylar	15
nylon	6
organosols	20
parting compounds	34
phenolic molding compounds	3, 9, 26, 30

C264

Materials	Supplier
pigments	15, 29, 5
plastisol	20, 7
polishing compounds	15, 20, 27 4, 5
polyester resins	15, 20, 29, 27, 6, 7
polyester resin colorants	14
polyethylene, powder, pellets	5
polynopylene	5
polysean seal compound	13
polystyrene expandable beads	20, 24, 8, 33
polystyrene, pellets	5
polyurethane foams	20, 7
release paper	36
release sprays	7, 15, 17, 20, 21

Materials	Supplier
rubber, room temp. vulcanizing	1, 15
sealers	34
sheet, rod, tubes	6, 7, 15, 20, 29
solvents	5, 20
styrene monomer	6, 20
styrofoam	15, 20
tempera, powdered	4, 20
thickeners, polyester resins	19
thinners	6, 20
thread compound, high heat	21
tinsel	20
Ultracal 30, gypsum cement	34
urea molding compound	3, 9, 26, 30
urethane foams	7, 20
vinyl dispersions	7, 20

This does not represent a complete list of supplies available. Refer to supplier's catalog for complete list of materials which they can supply.

LIST OF MATERIAL SUPPLIERS AND DISTRIBUTORS

Plastics materials are available from many suppliers. A partial list of suppliers, and their addresses are given here. The code number in front of each supplier is used in the List of Supplies on page 196 to indicate a source. A complete list of manufacturers can be found in the *Modern Plastics Encyclopedia*.

1. Adhesive Products Corp.
   1660 Bonne Avenue
   Bronx 60, New York
2. Admiral Coated Products, Inc.
   20 Railroad Avenue
   Hackensack, New Jersey
3. Allied Chemical Corp.
   Plastics Division
   40 Rector Street
   New York 6, New York
4. American Handicrafts Co.
   18-20 West 14th Street
   New York 11, New York
5. Brodhead-Garrett Co.
   4560 E. 71st Street
   Cleveland, Ohio 44105
6. Cadillac Plastics
   2427 6th Avenue, South
   Seattle 4, Washington
7. Copes Plastics
   Highway 100
   Godfrey, Illinois 62035
8. Dow Chemical Co.
   Midland, Michigan
9. Durex Plastics Division
   Hooker Chemical Corp.
   8 Walck Road
   North Tonawanda, New York
10. Eastman Chemical Products Inc.
    Kingsport, Tennessee
11. Edmund Scientific Co.
    Barrington, New Jersey 08007
12. Enthone Incorporated
    442 Elm Street
    New Haven 8, Connecticut
13. L. W. Ferdinand and Co. Inc.
    Simsbury, Connecticut
14. Ferro Corp. - Color Division
    4150 East 56th Street
    Cleveland 5, Ohio
15. Fry Plastics
    8601 S. Figueroa Street
    Los Angeles 3, California
16. General Electric
    Silicone Product Dept.

FOREWORD

The effectiveness of a school program is determined by classroom teachers. While administrative leadership helps teachers by providing good classroom facilities and adequate instructional materials, the classroom teacher is still the key person in every school.

The teaching techniques contained in this brochure were gathered from experienced teachers in many of the registered private business schools of the State of New York. Private business schools have long been recognized as leaders in teaching methodology unusually well suited to individual student progress. The ideas incorporated in this publication reflect the strong interest of these business educators in the progress of every student and the desire to motivate students to their maximum achievement.

Here are more than one hundred classroom techniques that have been used successfully. Some may be considered unconventional and perhaps will not function equally well for another teacher. It is hoped, however, that many of the suggestions will serve to stimulate teachers in both public secondary schools and private business schools to experiment with new techniques that may improve instruction.

Appreciation is expressed to all those teachers listed on pages 58-60 who contributed to the development of this brochure. Raymond A. Light, Associate in Business Education, coordinated the project under the direction of John E. Whitcraft, Chief, Bureau of Business and Distributive Education. The final manuscript was processed by the Curriculum Development Center with the technical assistance of the Bureau of Publications.

SUGGESTIONS FOR IMPROVING INSTRUCTION

IN

TYPEWRITING

Good pupil-teacher relationships contribute
to the learning situation.

OBS 281
SCL

TYPEWRITING 1
(Beginning)

SENTENCE METHOD

Students in beginning classes typewrite a sentence the first day. Examples are: feed the deer; the deer feed, etc. Note that only the strong first and second fingers are used. The sentence method, with the emphasis on double-letter words, not only makes the student feel accomplished but makes him sound that way.

FINGERING

Students who have difficulty with keys jamming, faulty spacing, or squeezed letters, may benefit from being transferred to an electric typewriter.

ENCOURAGE

The most important period for the beginning typewriting student is during the first month of instruction. During this time, each student must be observed constantly. When proper posture, fingering, and technique are learned well at the beginning of the course, the student, and teacher, will "breeze" through the remainder of the year.

If a student seems to make little or no improvement in basic typewriting technique during the first six weeks, have him repeat the introductory lessons to the keyboard. It will be well worth the extra time expended. As a result of this fresh start, he will gain confidence and usually substantially improve his basic technique.

NUMBERS

Numbers are learned early. If a student can move his finger from j to u successfully, surely he can continue up to 7. Practice the figures in the current date each day. After the keyboard has been thoroughly covered, type the complete current date (month, day, year) each day.

STEPPING UP THE NUMBERS

"W E - 2 3 drills" notwithstanding, a slower approach to the reaches of the figure row tends to lead to a most unusual control. Students should be taught to feel their way up the banks of the keyboard, working from home row to top row and touching the middle row en route. This technique in learning the reaches to the figure row fosters greater accuracy and confidence.

In reaching to the 2, students will be instructed to reach from the s key, touch the w, and return to the s key after striking the 2. In reaching to 5, they are taught to touch the r, 4, and reach one key to the right. In reaching to 6, they touch the u, 7, and reach one

key to the left. This "feel and reach" technique also works miraculously when applied to the special characters and symbols.

Some teachers believe that most typewriting texts introduce numbers too soon, but with this approach even the slowest student is able to master the reaches to the numbers and special characters with a minimum of difficulty. While the typing of numbers will be slower at first, the greatly increased accuracy will prove to be worthwhile in the long run.

MOTIVATION

During each drill period, review the keyboard with special emphasis on a particular letter, number, or sign. Time the drill; conduct several short timings.

Raise such questions as:

"How many typed at least 15 words a minute?" (The rate should be low enough to include almost every student.)

"How many typed for one minute without error?"

"How many improved this time?"

Each student should raise his hand in answer to at least one of the questions.

Changing the class pace often will also motivate students. Changing pace prevents boredom.

SHORT TIMINGS

Short timings should begin very early in the course. During the first lessons, for instance, students may be timed to see how many correct "the's" they can type in a 10-second timing.

SPURT TO SPEED

The following type of one-minute speed drills has been highly successful in achieving speed <u>with</u> control: Duplicate (on one sheet of paper) a series of paragraphs graduating from 30 to 90 words. Each paragraph is to serve as the basis for a 1-minute timed writing. Students may be directed to start working on this drill copy as soon as the entire keyboard has been covered. The aim of the drill is to complete each paragraph in one minute without error. The student is instructed to proceed to the 40 word paragraph only after he has completed the 30 word paragraph without error. The teacher maintains a record of each perfectly completed paragraph.

Alternating 1-minute speed spurts--with perfect copy as the aim for the first timing, all-out speed as the aim for the second timing, and speed with control as the aim for the third timing--will stimulate the development of speed, and with control.

DON'T BE SATISFIED WITH LESS--SET STANDARDS

The teacher who is effective enough to demand high-quality work and to reject as unmailable (therefore unacceptable) any piece of work that fails to meet these high standards will receive quality work from her students. A teacher can stamp out strikeovers and other evidences of sub-standard work by refusing to accept an entire lesson where these faults occur.

CHALKBOARD QUOTATIONS

One variation that a beginning typewriting class will enjoy is the placing on the blackboard each day a quotation from poetry, philosophy, or folk sayings. This quotation is typewritten by each student at the top of the page before starting the day's work. After the keyboard has been covered, it is wise to use quotation marks around the quotation and identify the quotation as to source.

CHECK AND DOUBLE CHECK

To give proofreading a portion of its tremendous importance, penalize poor proofreading of 5- and 10-minute timings by deducting one additional error if any errors were not found and circled by the student.

CLASSROOM MANAGEMENT--EVER ON THE ALERT

Students are instructed to type selected drills for a specific purpose or are given directions for typing a particular type of application. They know that papers will be collected at the end of the daily typewriting class, but are unaware as to whether they will serve as a simple review practice or as a test to be recorded. Consequently, they put forth their maximum effort each day to complete every exercise in the allotted time and without wasting paper. The graded papers are returned to students when a particular typewriting practice was intended as a test.

CLASSROOM MANAGEMENT AND SPEED BUILDING

The following technique is an excellent procedure for getting the period off to a good start and for building speed:

Before the class enters the room, place on the chalkboard instructions for the day's practice drill. The class has previously been informed that the aim is to typewrite as many lines of the drill as possible in the allotted time. The five minutes allowed for this activity permits the teacher to complete the necessary preliminary work before the actual class begins. The number of lines finished by each student is recorded each day, thus providing purposeful drill as well as a record of attendance.

It is interesting to note the gradual increase in the number of lines finished as the days pass. Call attention to this increase frequently by listing on the bulletin board the names of the top three typists for the week.

IMPROVING TYPEWRITING SKILLS BY SETTING INDIVIDUAL GOALS

Every typewriting teacher is interested in having each student become an effective typist and meet the speed and accuracy requirements of the course. By giving each student an individual goal, and by periodically revising these goals, there will be few students who will not have reached the course requirements.

Some steps suggested for selecting these individual goals are as follows:

1. An individual progress card is kept for each student. This card provides space for recording the date, gross speed, net speed, number of errors, and general remarks. The card is ruled to accommodate 50 different timed writing scores as well as space for recording the student's beginning and ending typewriting scores. This card is also valuable as a source of information for a placement office.

2. During a student's first course in typewriting, a record is kept on the card of scores obtained on 1-minute, 2-minute, and 3-minute timed writings. At approximately the tenth week, the student should be given his first goal. The basis for arriving at this goal is described below.

    a. Based upon the student's speed and accuracy range as indicated by the progress card, the teacher projects the student's typewriting ability to the end of the first term. The teacher projects the student's achievement based on 3- or 5-minute timed writings, using net scores for comparison purposes.

    b. At this point, it becomes the teacher's responsibility to review the student's various habits which directly or indirectly will affect typewriting progress. These might include physical limitations, mental attitude, position at the typewriter, stroking ability, reading ability, and previous typewriting experiences--plus any other history which would alter the student's progress.

    c. The teacher will now decide on the student's final goal for the first term. This goal will be recorded on the progress card and a conference

planned with each student. During the conference the teacher should explain to the student why and how the goal was set. Some of the purposes of setting this goal are:

(1) To help the "late starter" reach the requirements of the course.

(2) To keep the student with apparent potential striving for more and more speed and accuracy.

(3) To make every student realize that the teacher is not satisfied with less than the student's best efforts in typewriting.

(4) To demonstrate to the student that the teacher has confidence in his abilities and that by following this advice will reach the goal that has been set.

During the conference it should be made clear that the student will be expected to practice until the goal is reached. If necessary, the teacher will conduct after-class lab periods and timed writings to help him reach his goal. It is important for the student to realize that the prime responsibility lies with him and that the teacher cannot do the work for him.

This process of goal setting is repeated for each semester that the student is enrolled in a typewriting course. During the closing weeks of a semester, the teacher must analyze and resolve the problems that occur in connection with any student's reaching the goal that has been set for him. A student who has not reached his goal must be given every opportunity to reach that goal, and the teacher's work is not done until each student has been given such opportunities to achieve his individual goal.

TYPEWRITING CHARTS--MOTIVATION

Keep two large charts that students can easily read.

Chart I. A permanent chart presented as a graph which shows highest speeds attained by students. Whenever possible have the students maintain the chart.

Chart II. A movable type progress chart which shows weekly speeds attained by each student. This variety of chart is often kept by typing student names on tags which can be pinned to a bulletin board.

MAKING CORRECTIONS

Students are apt to have difficulty realigning their papers for making a correction once the paper has been removed from the typewriter. Use as instructional material a paper for each student that the student has previously typed and which contains a spelling error. Require each student to erase the error, reinsert the paper into the typewriter, and type the correct letter.

The technique of using a paper containing an error that the student has previously typed is also effective for teaching the use of the half-space key or the technique of half spacing.

TYPEWRITING SPEED--USE OF DISPLAY

Many students learn the use of the typewriter in high school in the tenth year, with a minimum of subsequent practice. When they subsequently enter a course providing advanced typewriting instruction, they frequently attempt to type too rapidly in relation to their present skill.

A most successful remedy is to display perfect timed writings on the bulletin board so that all may see and check for themselves. In addition, any student whose paper is displayed may be given extra credit for his accomplishment. If, for example, he has a perfect paper on Thursday, a perfect writing may also be recorded for Friday. He thus receives double credit. It is interesting to observe the effect of this incentive on a class--errors soon begin to decrease and speed increases.

TYPEWRITING SPEED--THE RELAY TECHNIQUE

Classes like to typewrite in unison. They especially like the "Radio City Rockette" drills made up of sentences composed of three- and four-letter words. Drills of this variety give the student the opportunities for reaching to new speed accomplishment. One use of this type of drill is as follows: First, practice the sentences in unison to set a pace; one row of students is then instructed to type the drill as quickly as possible and upon completion to return the carriage with a quick flick of the wrist; as soon as the last student in the row completes the sentence, the next row immediately begins. This "relay team" technique provides an excellent incentive for speed development.

With a little practice, it will be found that a class will not only pick up considerable speed but will also enjoy the process.

COMPARE ACHIEVEMENT ON SPEED AND ACCURACY WRITINGS

To show the student where he is failing in speed development, give 3 one-minute takes for speed alone (no penalty for mistakes); then administer 3 one-minute takes emphasizing accuracy. Finally, ask each student to compare the results of the two series of timings. The student will soon discover either his own tendency toward error or his need for conscientious speed development.

AN INCENTIVE TO HIGHER SPEED--THE RAPID TYPIST CLUB

The first challenge that presents itself is eligibility for membership in the Rapid Typist Club. Once a week the student executes test drills. These tests start with three- or five-minute timed writings and increase to ten and possibly to fifteen minutes. The student's goal in the longer writings is to achieve 50 or more words a minute. Once a student attains this speed of 50 w.a.m. or more, she automatically becomes eligible for membership.

Club meetings are held once each month and as part of the club's activities a timed writing is administered and awards made based upon the results attained. The minimum requirement for receiving an award is the typing of 55 to 59 words a minute, allowing a maximum of 10 errors on a 15-minute writing. The next award category is 60 to 64 net words, followed by 65 to 69 net words, then 70 to 74 net words.

The awards for rapid typewriting consist of attractive gold pins with numerals which indicate the speed reached. The competitive spirit continues among club members to earn a special award of typewriting 75 net words or more during a 15-minute writing. This special award permits the student the choice of the most recent edition of the SECRETARY'S HANDBOOK or the latest COLLEGIATE DICTIONARY. It is presented to the successful candidate by the principal of the school.

SUGGESTIONS FOR IMPROVING INSTRUCTION

IN

SHORTHAND

The overhead projector is an effective
teaching tool in many business education classes.

AN APPROACH TO EFFECTIVE STUDY OF SHORTHAND

Basic comprehension can be unlocked with three keys:

The Phonetic Key. Words are written exactly as sounded, and this key takes the word apart by sounding aloud each syllable--each outline--of the word.

The Image Key. Shorthand is a language of signs, and this key keeps inscribing these signs on the mind's blackboard, serving as a memorizer, reviewer, and constant giver of outlines.

The Correlation Key. There are interrelationships between outlines and this key systematically renders more dynamic and lasting memorizations of short forms, phrases, and basic rules of shorthand.

IMPORTANCE OF LEARNING BRIEF FORMS

Take three to five minutes each day to dictate the day's brief forms. Have the brief forms transcribed, checked by exchanging papers, and the perfect papers given to the teacher. (Perfect papers should be perfect both as to outlines and transcripts.) Students with other than perfect papers are considered not to have mastered that phase of the day's lesson.

PERMIT STUDENTS TO USE THE CHALKBOARD

Begin the first shorthand class by having students write the different shorthand characters as they are put on the board. When classes are small, the teacher may send students to the chalkboard (or overhead projector) to write. This enables her to see readily how well students are progressing.

KEEP THE INITIAL PACE SLOW

During the first two weeks of the term, a slow rate of presentation is set, usually a new lesson followed by a thorough review every third day. In other words, for the first eight sessions 3 or 4 lessons are taught. This will make it possible to give every student a thorough comprehension and "feel" of the phonetic basis of shorthand, proper penmanship, and correct size of outlines.

Beginning with the third week of the term, one complete lesson in the textbook is presented daily. Fortnightly tests are given either in the form of word dictation or mimeographed sheets. Corrected tests are returned to students and a remedial lesson follows.

Each class period is started with a dictation of the special vocabulary and short forms of the homework lesson. This dictation is followed by a short business letter of low syllabic intensity.

Constant emphasis is placed upon correct spelling, punctuation and paragraph structure in order to lay the foundation early for transcription.

Assignments for home practice are given each day. Two days prior to the formal mid-year examination, as well as before the final examination, a complete review is given.

As an additional incentive, students who are encountering difficulty are invited to meet the teacher periodically for extra help. This is especially beneficial to the student who has missed a lesson as a result of an absence.

To avoid monotony and to maintain a high level of interest on the part of students, the method of presentation should be varied through the use of the inductive, deductive, project, work sheet, and open textbook methods.

INTRODUCTIONS IN SHORTHAND

For interest development, introduce students to the class (via shorthand) as soon as principles governing the writing of their names have been presented. This procedure can be extended to faculty members, the administration, office staff, and other workers with whom students are associated daily.

USE THE CHALKBOARD FREELY

The chalkboard should be used constantly for illustrations of concepts that can be presented visually. Teach standing and let the chalkboard help to vitalize the lesson.

AIM TO BUILD VOCABULARY AND RELATED INFORMATION

Supplement lessons with valuable additions from a variety of supplementary sources of information. In this way students will learn not only shorthand but a wealth of related useful knowledge.

Students become dictionary users when the teacher is able to impress upon them the importance of vocabulary building. The teacher should make sure that every possible translation is given for an outline, including the brief forms, and should seek ways to foster the use of the dictionary for correct spelling and word meanings.

DICTATION

Teach advanced students how to use a stopwatch for dictation and give them the opportunity to work with slow or new students. In this way, advanced students are given the opportunity to dictate and take dictation from a number of different dictators.

PEP WITH PROMPTING

When a student is reading from shorthand plates in the textbook, overcome daydreaming and boredom of the other members of the class by asking the class to prompt the reader when necessary. The class then becomes more attentive and will follow the reader more closely.

DICTIONARY CLUB

Students experiencing difficulty with spelling may form a dictionary club. In reading new or alienated material in shorthand, when a student is "stumped" by a word, one of the members of the dictionary club is called upon to supply the word. This technique has proved effective for helping students who may be having difficulty reading fluently but who are able to grasp shorthand theory.

ENTHUSIASM--A COMMON DENOMINATOR FOR SUCCESS

The enthusiastic teacher keeps the shorthand class alive and alert; the class moves at a rapid pace and as a consequence, good learning results are usually obtained.

Give students the necessary confidence and encouragement. By constant challenge, keep students alert; by commendation and enthusiasm, keep them relaxed and cheerful.

RELYIN' ON RELAYIN'

If you can't read shorthand, you certainly can't write it! Students have a tendency, however, to tire of reading sessions because they do not realize that facility in reading from shorthand is not only beneficial but very essential to shorthand success.

Why not conduct races to keep students interested and motivated? Competition has always been the basis of success--shorthand being no exception.

Time students as they read, and record the top speed and student's name on the board. Encourage students to compete with themselves to better their own top record.

As an alternate procedure, organize the class into teams of four or five students and have each team read a selected passage under timed conditions. The team with the best timing wins the race.

The feeling of competition will increase reading speed which is the basis of speed in dictation. With a little competition this can be accomplished with genuine interest and enthusiasm--that all important element to success.

SCRAMBLE PERK-UPS

Many times a "blue Monday" falls on a day other than a Monday. On these days, students seem disinterested and unresponsive; the atmosphere prevailing is certainly not conducive to learning. One technique that will help to lift students' spirits is the use of scrambled sentences.

If today's lessons were 20 and 14, (Gregg Shorthand Simplified), for example, I might write in shorthand on the blackboard the following scrambled sentence comprised of words from these lessons:

meant mend to mother the leather brother for chair but she help waited to her.

Key: Mother meant to mend the leather chair, but she waited for brother to help her.

women examine editor wasted about many glad to the from the will be letter money the.

Key: Many women will be glad to examine the letter from the editor about the wasted money.

Scrambled sentences cause students to come "alive"; each student wants to be the first to unscramble the jumbled words. After two or three such sentences, a class will have lost its "blues" and be ready to go back to work.

VARY THE NATURE OF DICTATION MATERIAL

In your class dictation, avoid using for subject matter only business letters. Use a variety of articles taken from current literature. You may also dictate speed pointers and other tips for the beginning secretary.

Urge your students to use dictation records and tapes available at various dictation speeds for supplementary out-of-class dictation.

PROVIDING FOR INDIVIDUAL DIFFERENCES

Continually stimulate students to strive for greater shorthand speed by setting aside a few minutes of the class period, preferably at the end of the period, to dictate a series of letters (at least three) at gradually increasing speeds.

Students should be instructed to try to take each of the letters dictated and to hand to the teacher the letter dictated at the highest speed that they are able to transcribe (or write) in its entirety. This teaching technique enables each student to take dictation at his own best rate; at the same time, it provides for the varying abilities of your class.

USE OF TAPE RECORDER

Tape record several letters from your shorthand textbook for the use of students in developing speed. These tapes may then be used out of class for additional dictation practice.

The letters may be recorded at a variety of speeds--60, 80, 100, 120 words a minute--with a short preview before each take. Since students gain speed by taking dictation of easy, familiar material, the letters should consist of relatively simple content.

Students should be encouraged to practice individually with the tapes. They are familiar with the teacher's voice and seem to enjoy this opportunity for additional practice. Those students who have been absent have this opportunity to make up for lost class time.

TIPS ON METHODOLOGY

Theory. Teach all of the shorthand theory as soon as possible!

1. A new word injected into a sentence and its structure explained is more impressive and is apt to be remembered longer.

2. Instruct students to record in shorthand on homework papers turned in each day, the day and month of the year copied from the board. Constant usage in this manner improves the outlines and saves the teacher from devoting a complete lesson to the days and month of the year.

3. Correlate related theory when first presented. i.e., ing, ings, ingly.

4. Tie the varying uses of strokes together. When the use of ish for short and ship is presented, review all uses of ish. Follow this pattern for all strokes.

5. Provide constant drill on derivatives, especially brief form derivatives. This practice insures instant recall of the root word and increases the ability to recognize and execute known outlines in new words.

Penmanship. Emphasize that shorthand is written not for beauty but for ease of writing and transcribing.

1. As soon as students begin to write in sentences, guide penmanship. Dictate and permit students to copy from the textbook; call out such directions as "way up to the d--," "shave the initial 'a' on down strokes," "o--deep and narrow," etc.

Aes 295

2. During the first ten weeks, it is advisable not to insist, criticize, nor interfere in any way with the student's development of his own individual penmanship style.

Speed. Speed is worthless without readability.

1. A little trick for students who may be having difficulty acquiring dictation speed is the "backtracking for the forward push" technique. Use a short letter of between 60 and 100 words. (See letter 241 of the Gregg Shorthand Manual, Second Edition, as an example.) The letter might be dictated as follows: Dear Friend your--Friend your business--your business definitely--business definitely makes--and so on. The letter is then rewritten. Speed may be doubled in this manner.

A FEW WORDS OF ADVICE

1. Be calm and relaxed. Your class is a reflection of you.

2. Praise success; minimize failures or mistakes. Find something to praise every pupil for every day; the less a student has to praise, the more she needs it.

3. Realize that every skill learner is entitled to practice without criticism and observation.

4. Remember that a skill must be learned. You acquire technique from improved performance.

5. Dictate in such a way that any stranger would not know you are a teacher.

6. Keep students enthusiastic.

7. Teach students how to study shorthand theory and how to use the transcript.

8. Build speed on easy material.

9. Remind students to "keep writing" when working for speed.

10. Keep "speed takes" short.

11. Repeat "speed takes" over and over again.

12. Following every "speed take," be sure to drop back for control.

13. Leave writing habits alone.

14. Let students know what you have set as goals.

SUGGESTIONS FOR IMPROVING INSTRUCTION

IN

TRANSCRIPTION

The voicewriter can be used effectively
for small group instruction in shorthand.

TEACHING IDEAS

Students must be constantly encouraged to check carefully for accuracy every piece of transcribed copy. New words encountered and words misspelled should, of course, be checked with a dictionary. Students will strengthen their vocabulary and spelling by developing a vocabulary list of these words and their meanings. Once each week the word lists should be collected by the teacher and checked against errors indicated in the student transcripts. This practice will cause students to proofread more carefully, to use the dictionary effectively, as well as serve to strengthen student vocabularies.

Another technique is to assign ten words each day as part of the regular homework for spelling, syllabication, word meaning, and correct shorthand outline. Give a test periodically on these words and provide extra credit for students who can handle these word lists without error.

THE SPIRIT OF EMULATION

When the instructor writes in shorthand on the chalkboard slowly, her students will follow the example. When the teacher writes her own shorthand fluently on the chalkboard, the class is more interested than when following the notes of the textbook.

Write slowly to explain, then repeat again at a faster rate. Give students the urge to write faster with repetition, thus learning by doing and seeing. Correct shorthand outlines are learned more readily by assimilation than by being memorized.

FOUR PROCEDURES THAT HELP INCREASE TRANSCRIPTION RATE

1. Use a stop watch to time the transcription period. Check individual students from the time the typewriter carriage stops because of a transcription "barrier" until the problem is resolved and the student continues on. This may also include carriage "stops" caused by the need for correcting an error.

2. Demonstrate the techniques of making an erasure easily and quickly:

    a. With the right hand, pick up the eraser. Simultaneously with the left hand, pull the carriage to the left or right.

    b. While the right hand is moving toward the cylinder with the eraser, the left hand should twirl the platen up to the erasing point.

    c. Make the erasure, carefully brushing the erasure crumbs from the machine.

d. As the right hand places the eraser back on the desk or in the desk drawer, the left hand should return the carriage to the typing point.

Have students practice the steps indicated above; practice at the count of 1, 2, 3, 4 many times. Follow this practice for one month and note the increase in the transcription rate.

3. Instruct each student to keep a list of all words misspelled during the period of a month. Words repeatedly misspelled should then be listed on 3 x 5 index cards which can be arranged alphabetically and kept near the typist as she transcribes.

4. When working for speed, push students several words a minute above the rate set as a transcription goal.

MAILABLE LETTERS

One of the prime achievements of a course in transcription is the mailable letter. Many factors contribute to this end. Prominent among them is the ability to erase and make corrections easily, good proofreading habits, reading shorthand notes for meaning of words in context, good vocabulary, spelling ability, and, of course, common sense.

In many offices there is no such thing as a correctable mistake. Employers in these offices expect such errors to be caught by the stenographer before any letter is presented for their signature.

In an effort to help students accomplish this end, letters are read back in class with all marks of punctuation designated even before actual transcription at the typewriter takes place. Thus, when the student actually starts the task of transcribing at the typewriter, he is thoroughly familiar with at least one major element--punctuation.

In order to produce an acceptable transcript in a short space of time, the student must have complete control of the typewriter and an adequate typewriting speed. Careless errors, poor erasures, and smudges must be eliminated in order to produce the desired objective--a mailable letter.

IMPROVING QUALITY OF DAILY TRANSCRIPTS

A simple technique for improving daily transcripts is to have unannounced daily tests. Rather than have students anticipate the test days, the teacher should collect the daily transcripts each day and announce the test only after papers have been turned in.

In this way each student does his best work each day, not knowing but that the day's work will be evaluated by the teacher as the weekly test. Not only does this practice tend to improve the daily transcripts,

but the student who is inclined to become upset at the announcement of a test, overcomes the nervous tension of a weekly or bi-weekly test.

SUGGESTIONS FOR IMPROVING INSTRUCTION

IN

SECRETARIAL PRACTICE

The atmosphere of any business classroom laboratory should approximate that of a well-run business office.

PRACTICAL OFFICE TRAINING

Your secretarial practice class may be made more practical and effective by supplementing the text with actual office tasks. Supplement your textbook with several work assignments of a type required in local business offices. These assignments may be prepared with the help of executives from several business organizations. Select the office tasks so that students are given an opportunity to work with many of the common office reference books and other materials encountered in modern business offices.

ORGANIZE THE CLASS AS AN ACTUAL OFFICE

Conduct the secretarial practice class periodically as an actual business office. Appoint one student as office supervisor. All completed correspondence should then be checked by the supervisor for accuracy and enclosures before giving her signature of approval. The letters are then returned to the "stenographers" where they are folded and inserted into the accompanying envelopes ready to be mailed.

No grades are assigned, but student stenographers understand that their rating as an employee of the office will depend upon the quality of their performance. Perfect work is considered to be "top" performance; mailable work with acceptable word substitutions and corrected errors, "average" performance. Work which includes any misspelled word, a bad erasure, an incorrect word division, or any other transcription fault is considered unmailable and must be retyped until acceptable.

START FILING INSTRUCTION EARLY

Although filing instruction may not be started until several weeks from the start of the school term, students may begin learning to file properly from the day school begins in the fall. As they are instructed to write their names on cards, surname first, comma, given name, etc., remind them that this preparation for later alphabetizing is called "indexing." As students assist in the collecting and arranging of cards in groups of A's, B's, C's, etc., remind them that what is really happening is that they are doing what the file clerk refers to as "rough sorting." If there are names with a prefix, such as Ellen St. Croix, the class is also given an opportunity to learn how such a name is correctly filed.

Another means of teaching filing in a practical way is to give students an opportunity to alphabetize papers that are collected in class. This makes it possible for students to be seated in other than alphabetic order and yet provide the teacher with an efficient means for handling homework papers.

When formal instruction in filing is begun, it is sometimes interesting to have members of the class exchange exercises that have been filed. This provides the opportunity to cross check upon the accuracy of one another in the class and emphasizes the importance of a uniform system of filing in any business organization.

WHAT'S MY NUMBER?

Let's be realistic in teaching Soundex filing! Use the names of students to illustrate the system used in the Social Security and Motor Vehicle files--two files in which most students' and parents' names will eventually appear.

IMPORTANCE OF GOOD TELEPHONE TECHNIQUE

In a modern business office a secretary must be of help to her employer through her efficient use of the telephone. Help your students to appreciate the importance of

1. a positive, pleasing telephone voice
2. asking questions; getting names and messages correct
3. leaving messages where they will be found immediately
4. memorizing telephone numbers, voices, and names that are frequently encountered
5. temperament and attitude. They show over the telephone.
6. having information at one's finger tips or where it can be quickly located
7. following through with any promises made during the telephone conversation
8. trying to be helpful to <u>every</u> caller

INITIATIVE AND ATTITUDE

There are many instances where a secretary, because she is a good one, actually runs a goodly portion of the activities of a business. Because she knows the business thoroughly, her employer does not hesitate to trust it to her care. Her attitude toward herself, her employer, the firm, and her associates will, however, often influence the degree of responsibility entrusted to her.

Help students to appreciate that initiative is basic to job success. Initiative is more than a quality to be talked about; it must be practiced. Ask students to look at the word <u>initiative</u> and observe the number of "eyes" that it contains. This implies the ability to see great detail. Stress that a good secretary is not afraid to make a decision or to take action on her own. Mistakes may be made, but employers like employees who shoulder a little responsibility.

Employers also like employees who grow with the business and who may some day be capable of becoming the head of a department, an office, or the entire organization. Naturally, every employee wants a

better job, but he must be prepared for it when the crucial time arrives. Stress with students that initiative involves planning on the job for jobs higher on the organizational ladder. Initiative involves planning, education, study, and forethought.

ACTUAL OFFICE EXPERIENCE

All secretarial students are required to work 36 hours at a reception desk which places them in an office-type atmosphere. To identify herself and her responsibility, the student places a placard on the desk which reads "Student Secretary for the Day, Miss Susan Brown."

Some of the duties for which she may be held responsible are:

1. Answering all incoming phone calls

    a. Recording messages
    b. Delivering messages promptly and correctly
    c. Screening calls to see that teachers are not interrupted unnecessarily

2. The sale of small supplies

    a. Making change
    b. Seeing that supplies are available for sale

3. Office dictation

4. Assistance to teachers

    a. Typing stencils
    b. Operating duplicating equipment
    c. Recording data in the proper record books

5. Assisting with office filing

6. Greeting visitors

Duties such as these will provide the opportunity for a student to demonstrate her initiative and good judgment as well as her office skills. Placement personnel will also welcome this opportunity to appraise a student's capabilities and be better prepared to recommend her upon graduation for a suitable position.

SUGGESTIONS FOR IMPROVING INSTRUCTION

IN

ENGLISH FOR BUSINESS

A variety of library resources should be available to the business student.

HELPFUL HINTS FOR TEACHING ENGLISH MECHANICS

The student who has studied English for many years frequently needs new directives and motivation for continuing the study of the subject. The right mental attitude must be formed before a teacher will receive the desired results.

The business student must realize that in order to succeed in many types of employment and particularly in office employment he must have a good command of the English language--accurate and action-producing. He must realize that he will be expected to be able to apply the fundamentals of English grammar he has learned; he must also appreciate the need for a clear but forceful writing style, powerful enough to impress the reader and stimulate him to the desired action.

In order to strengthen the foundations of sentence structure, the teacher should be sure that students can distinguish between a complete and an incomplete sentence. Considerable time must also be devoted to the re-teaching of the principal parts of speech and fundamentals of sentence structure. It is desirable for many students to keep a notebook of definitions of the parts of speech and sentence components. Students are apt to forget the difference between a phrase and a clause, between an object and a predicate nominative. Let it be emphasized, however, that the explicit meaning of terms is not nearly so important to the student as the understanding of how they are correctly applied. A program which combines the building and analyzing of sentences with the writing of business letters is therefore helpful.

Exercises which provide practice in such aspects of English grammar as agreement of subject and predicate and correct pronoun forms will strengthen the student's understanding of sentence structure. The principal parts of certain verbs are also troublesome to some students. Reciting these verb forms in unison is often helpful. If the student remembers that the past tense needs no helper but that the past participle does, he usually has less difficulty.

Students find it interesting to work together in class building sentences. The adding of words, phrases, and clauses to a given framework of a sentence can be made both profitable and enjoyable. If students have not been taught to diagram, there is often an immediate psychological block. However, since some students understand better when they can visualize, some form of sentence diagramming should be presented. A brief review of a few simple diagrams usually is sufficient for those who have been taught the process. The simple device of underlying the main elements of the sentence, and using parentheses to set off phrases, brackets for clauses, and arrows to show the relationship of modifiers also enables students to clarify the relationships of words in a sentence.

If students can be made to realize the importance of the letter in the business world, they will have a greater desire to improve their written English. Via the medium of composing carefully constructed

business letters, students will have an opportunity to demonstrate their facility with English grammar, sentence structure, punctuation, vocabulary and spelling. At the same time, the teacher will be able to discover the principal difficulties of each student, and both teacher and student can work together more easily toward the goal of perfect English.

PUNCTUATION AND CAPITALIZATION

Good punctuation and correct capitalization are made a practical reality by having the rules learned as applied and repeated as assignments are corrected. By learning WHY, often for the first time, students understand the importance and necessity of correct capitalization and punctuation and the definite use of each punctuation mark.

PENALTY FOR ERRORS

Every business teacher knows the feeling of frustration when a student is heard to break a basic rule of English grammar. Occasionally, when students are heard making such errors, try this little game. When a student is caught making an error in English, either in class or out of class by his fellow students, penalize him a penny. Encourage every member of the class to be alert to these infractions. Use the pennies collected for some worthwhile class activity.

THE DAILY SPELLING LIST

Dictate twenty-five words each day, but give credit to a student only for 100 per cent accuracy in the spelling of the words selected. A weekly spelling test may then be given covering the words included in the lists of the past week.

THE SCHOOL NEWSPAPER

The school newspaper provides a proving ground for most of the communication skills the student has been taught in his secretarial training. Gathering the newspaper content requires research; writing the copy requires a knowledge of English, spelling, punctuation, form of layout, and artistic talent; typing and stenciling for the project requires accuracy; painstaking proofreading is necessary at every point in the process. Complete knowledge of the operation of the mimeograph machine is essential. Collating, selling, and accounting for funds involved provide further experience in matters which may be of help in future office positions.

LOOK UP AND LEARN

As a means of building vocabulary, have your students read the editorials in one or more local newspapers. Request that new words encountered and their definitions be written by each student in a notebook. Shorthand students may also be instructed to write the shorthand outline for each new word.

11310

CLASSROOM TELEGRAMS

Teaching students to condense a message helps to strengthen their writing ability. For example, the teacher may either relate a story to the class or have students read an article from a specified business maga 'ne. Students are then requested to summarize the story or article in 10 to 15 words and to typewrite the "telegram" within 10 or 15 minutes, depending upon the length of the article.

DEMONSTRATE THE EFFECTIVENESS OF THE PERSONAL DATA SHEET

Many students lack confidence in their ability to compose a good business letter, particularly a letter of application. As the teacher knows, a personal data sheet with concise accompanying letter is frequently used with success.

Students must, of course, appreciate that a short, carefully written letter, whether it be a letter of application or an ordinary business letter, is essential today. Every business letter should adhere to the five C's of good letter writing--courtesy, conciseness, clearness, correctness, and completeness.

In order to prove to students the effectiveness of the personal data sheet in writing a letter of application, one teacher on several occasions has demonstrated its use to her class by answering a blind "help wanted" advertisement. The reply from the employer was then exhibited to her class.

This demonstration has emphasized dramatically to students the effectiveness of preparing a letter of application in this particular form. Students should also appreciate the wisdom of preparing such a letter with utmost speed. If possible, the letter should be completed within an hour from the time the advertisement first appears in the newspaper. For any local job opening, it should then be taken directly to the newspaper office rather than lose the time necessary for having the letter pass through regular postal channels.

MONITOR RADIO AND TELEVISION BROADCASTS

Interest in developing good grammar and a better vocabulary may be created through the technique of recording errors of this variety heard on radio and television programs. When each student is made responsible for one new word a week that is new to him, with its proper pronunciation, meaning, and use, or one grammatical error used in apparent good faith by a radio or television announcer, he is made aware of his own limitations in speech.

SUGGESTIONS FOR IMPROVING

ECONOMIC UNDERSTANDINGS

Everyone can profit from instruction in applied economics.

A HYPOTHETICAL INVESTMENT

Many students hold preconceived ideas and prejudices concerning various facets of economics. This is especially true of the student's ideas of the corporate structure and its financial implementation.

With a mythical cash outlay of $10,000 to be invested by each student and $50,000 by the class as a whole, the world of stocks and bonds can take on a personal meaning. The suggestion that this money be invested immediately will usually be disapproved by most students. They will ordinarily prefer to withhold making a stock or bond purchase until such time as they are more confident of the past history of the investment. Thus the framework is laid for a concentrated study of the corporate structure and of the factors that affect the value of a stock or bond on the market.

With encouragement, students will visit brokerage agencies, make a study of such financial ratings as Moody's Manuals or Standard & Poor's Standard Corporation Records, read the Wall Street Journal, examine prospectuses, and learn a variety of terms that afford a better understanding of stocks and bonds.

After making their investments, students enjoy following the activity of their investment via the newspapers. A chart kept on the progress of the class investment of $50,000 also serves to stimulate interest.

In addition to the increased class participation in the learning process, there is a noticeable change in the attitude of students toward stocks and bonds as a means of future investment for them.

INJECTING A PERSONAL POINT OF VIEW

Ask each student to consider as his salary what might be considered an average amount for a beginning office worker. With this amount, request each student to work out, according to the principles learned in class, a budget that will fit his own needs and desires.

SUGGESTIONS FOR IMPROVING INSTRUCTION

IN

BUSINESS MATHEMATICS

Related arithmetic should be
taught in connection with appropriate topics.

READ NUMBERS ALOUD

As an introduction to the course in business mathematics, provide practice in the oral reading of numbers. It is surprising to learn that when a number has more than three digits many students will hesitate or stumble.

Some practice can be given by reading numbers as a group or as a class. Particular attention must be given to the reading by individual students, however, if maximum benefit is to result.

PENMANSHIP

Instruction, as well as constructive criticism, in the formation of figures will benefit students. It is wise to point out that careless penmanship frequently leads to confusion of the figure 1 with the 7, 3 with the 5 or 8, 6 with 0, and 4 with 0. As a result of the poor construction of figures, there is apt to be poor alignment which is another cause of inaccuracy.

COMPETITION

In the early weeks of a course in business mathematics, it is important to stress arithmetic fundamentals. To hold attention and create interest in class drill on addition and subtraction, this technique is suggested: Dictate a checkbook beginning balance; then indicate the amount of a check drawn. After hesitating a moment, dictate the amount of another check, then a deposit, then another check or two. To stimulate competition, allow a show of hands for the first completed result. Competition proves to the student that he is rusty and that mental lubrication is very good medicine.

REVIEW TECHNIQUES

When reviewing multiplication and division, illustrate short-cut methods that can be used. This will stimulate interest in the review. Use sales tickets, invoices, customer accounts, and customer monthly statements to add realism. This will tend to relieve the monotony of the review.

COMMUNICATION

Appoint students to go to the chalkboard to illustrate their solution of assigned homework. Then allow each student to explain his work for the benefit of the class. This experience will emphasize the importance of being able to explain one's logic in a solution to others.

GARNER WITH HONOR

In business, honor is a prerequisite. To stress this objective more fully, make it possible for students to use the classroom as a

laboratory. An honor system can be initiated through a self-check point system. Points might be accumulated weekly for such activities as the following:

Quick quiz	-	10 points
Class participation	-	10 points
Homework well done	-	2 points
Answering a challenging question	-	2 points

The various means of accumulating points must, of course, be explained to the class. Deductions from the weekly total may also be made for such infractions as failure to complete homework, talking, lateness, etc. At the end of the week, each student accumulates the points he has earned and submits his score sheet in a style that will conform to the model outlined by the teacher. He may report his score for the week in terms of points earned or, if the teacher prefers, as a letter grade. A letter grade might be based upon a scale such as the following:

A - 70 points or more
B - 60-70 points
C - 50-60 points
D - 40-50 points
E - Below 40 - unsatisfactory

SCORE SHEET

Student's Name.....Week of.....

I, on my honor, submit the following points:

Total..... Grade.....

SIMPLE METHOD FOR CHANGING A DECIMAL TO A FRACTION

Example: Change .1263 to a common fraction.

First, place 1263 as the numerator of a fraction.

Second, put a zero for each decimal place in the denominator and place a "1" before the zeros.

This will supply the correct number of zeros in the denominator.

If necessary, reduce the fraction to simplest terms.

Answer: $\frac{1,263}{10,000}$

TEACHING MARKUP

The conventional method of presenting the topic of Markup in business arithmetic is to supply the student a formula, such as

$$\frac{\text{Principal}}{\text{Rate}} = \text{Base}$$

Using the above formula, the student then learns to determine the selling price when the markup is based on the selling price.

Another method which has proved to be successful will be illustrated through the following examples:

1. Determine the selling price of an article costing $4.14 if markup amounts to 25 per cent of the cost.

2. Determine the selling price of an article costing $4.14 if markup amounts to 25 per cent of the selling price.

The teacher must first impress upon the class that the base is equal to 100% and that the basic formula is as follows:

Cost + Markup = Selling Price

The class is then told that to find the selling price when markup is based on the selling price one must divide by the cost expressed as a per cent. If markup is based on the cost, multiply by the selling price expressed as a per cent to find the selling price in dollars.

The solution to problem 1 above might be illustrated through the following "T" arrangement:

Formula	%	$	
Cost	100	$4.14	
+	+		Multiply
Markup	25		by
=			125%
Selling Price	125		

The solution to problem 2 above might be illustrated through the use of a simple "T" and with the formula written at the left

Formula	%	$	
Cost	75	$4.14	
+	+		
Markup	25		Divide
=			by
Selling Price	100		75%

QUICK QUIZ

At the start of the period, administer a short quiz by placing on the chalkboard as many problems as there are rows of students in the classroom. In this way, there will be a different question for each row. The first student from each row who is finished will be given the chance to go to the chalkboard and place his solution to any problem other than the one assigned to his row. He will earn an additional 2 points if his solution is correct. The examples are then checked at the chalkboard by the teacher. Each student at his seat corrects his paper and places a score of "2" on the paper if his solution was correct and a score of "4" if he was one of the "winners."

MULTIPLICATION BY MACHINE

Multiplication by adding machine poses no problem for the mathematically minded, but for those students who have difficulty with arithmetic fundamentals it is often confusing. To facilitate the teaching of multiplication on an adding machine, first explain the process of multiplication without the use of a machine. Tell students to multiply 8.75 x 431 arithmetically, for example. When the work is completed, ask "What did you multiply by first?" After some discussion, the correct answer is identified as being "one." Then ask, "What did you multiply by next?" At this point, the correct answer is readily identified as being "three." Then point out that actually the multiplication in this case was by 30--the result of moving the product one column to the left instead of placing it directly beneath the product of 1 x 8.75. Again, ask "What did you multiply by then?" After receiving the reply, "four," remind the class that actually the multiplication was by 400--the result of moving the product one more place to the left.

Now, when the teacher instructs the class to "move the multiplicand one column to the left on the machine each time you multiply it by a number from the multiplier," it becomes clear that what has actually taken place is that the multiplicand (in this case) has been multiplied by 1, 30, and by 400.

SUGGESTIONS FOR IMPROVING INSTRUCTION

IN

BOOKKEEPING AND ACCOUNTING

The overhead projector facilitates
instruction in bookkeeping and accounting.

AN ANALOGY

It has been found helpful to students if the teacher presents the bookkeeping cycle as being analogous to the playing of a hand of cards.

The Analogy

A Hand of Cards	The Bookkeeping Cycle
1. A hand of cards is dealt, representing the potential of the player.	1. The original investment (Assets; or Assets and Liabilities) are indicative of the financial condition of the proprietor (Proprietorship)
2. Cards are played according to the rules of the game and the best judgment of the player.	2. During the fiscal period, business is transacted by the proprietor. The bookkeeper records these events first in the form of business vouchers from which journal entries are made. These entries are posted into the ledger from which a summary is drawn in the form of a trial balance.
3. As a result, the player may either add to or reduce his score.	3. From this summary or trial balance, adjusting and closing procedures take place and the proprietor is presented with his score.
4. For the card player, this is a time for analysis, comparison, and reflection. He is then ready for a new hand of cards.	4. A detailed explanation of the result of operations is prepared in the form of an income statement. A new hand of cards is dealt in the form of a balance sheet.

AN ORIGINAL PROJECT

Bookkeeping, which involves a maze of detail that is essentially recordative, has the distinct goal of providing summary data (trial balance, financial statements and endless reports that call for a recapitulation of the accumulated detail involved). Every bookkeeping teacher will agree that there is a great difference between teaching bookkeeping students to understand the mechanics of record keeping and getting them to be a "thinking" bookkeeper. The student who records business data without the insight necessary to see how the part which he

is recording fits into the bookkeeping cycle as a whole is working blindly. It is this type of blindness that explains many of the errors leading to imbalance of the records, not to mention other shortcomings of records maintained by bookkeepers who cannot see in their "mind's eye" the total recording picture.

Developing bookkeeping "insight" in students is difficult. The project described below is suggested as one means that can be used to develop bookkeeping awareness of how each entry in a set of books, regardless of their form, fits into the total bookkeeping cycle.

The Project. Each student is asked to choose a type of business he would like to work for as a bookkeeper during the final weeks of the first year of bookkeeping. The student selects a business with which he is familiar or in which he is interested. Students will typically select from such businesses as: gas stations, grocery stores, beauty parlors, restaurants, farms, etc. The best project submitted by a student to one teacher involved a hamburger stand. The type of business selected is not as important as the student's knowledge of, or interest in, the business.

After selecting a business for his project (with teacher approval), the following steps are taken by the student:

1. A hypothetical balance sheet is drawn up for the business.

2. Original records (form of journals) are drawn up.

3. Transactions of the business are written out for one month (number and diversity are based on student ability, interest and other factors).

4. Transactions are journalized; journals are completely posted to the ledger(s).

5. Trial balance is taken.

6. Financial statements are prepared.

Rewards of the Project

1. Student interest is stimulated. The opportunity to work in a business of his own choice arouses momentary excitement.

2. Originating the bookkeeping system brings to life much of what was mere bookkeeping theory.

3. Hypothecating business transactions brings into play related information that the student has learned from other business courses.

4. The projects are individualized; no two students are working with the same data. Competition occurs; students make their projects as extensive and qualitative as their individual ability dictates.

5. The project provides a complete view of the bookkeeping cycle and dramatizes each step in the process. The project is the student's own creation; he has supplied the materials and all details and is completely familiar with them; he understands the correlation of each part of the project with every other part. The student has been "thinking" bookkeeping instead of mechanically recording data.

TEMPORARY AND PERMANENT ACCOUNTS

When the Balance Sheet Approach is used, one teacher starts with the question, "What do you know about the Alps?" When the word permanent is introduced, the teacher compares the Alp(s) of business with the Alps of Switzerland. Assets, liabilities, and proprietorship are the permanent accounts of a business--those which comprise the balance sheet of a business.

The teacher may then liken the accounts of the Income Statement to ice. Like the melting characteristic of ice, the accounts which comprise the Income Statement are temporary in nature. The key words alp and ice help the student to visualize the nature of the accounts that appear on these two principal bookkeeping statements.

Another question to be raised is, "What accounts customarily have debit balances; which credit balances?" The key words ace and lip may be introduced to help the student identify these accounts.

RELATE INSTRUCTION TO STUDENT EXPERIENCES

When introducing a class to bookkeeping, it is important to incite their imagination by relating the hypothetical situation to experiences encountered in their everyday life. If students are able to visualize a situation and actually live the experience, the problem will become more meaningful and result in greater student interest.

In presenting the permanent accounts elements--assets, for example--use personal assets as illustrations. These might be such items as a student's wardrobe, his savings account, or his jewelry. Liabilities can be illustrated by his obligation to a clothing merchant for new clothing, an unpaid medical fee to the family physician, or a mortgage held by a bank on the family home.

Use this technique to chart the fundamental equation and illustrate to the student how his own proprietorship is determined. Having determined his own capital, then substitute the assets, liabilities and capital of a business in a similar equation.

When discussing a transaction, use a situation in which any student could actually have had a part. For example, the transaction might involve the boarding of a bus for transportation to school, buying the morning paper, or shopping at a local supermarket. Such illustrations permit the student to project himself into the situation and facilitates his understanding of the effect of the transaction on the accounting elements. Every new account that is introduced in a transaction is illustrated by a "T" account and its effect on the accounting equation is explained at that time. If diagramming is essential in teaching English grammer, "T" accounts are essential in bookkeeping.

MINIMUM OUTSIDE PREPARATION DURING THE FIRST MONTH

Very little independent written outside homework is required during the first month of bookkeeping instruction, other than the completion of work partially completed in class. During the succeeding class session, the completed assignment is then checked and individual questions answered before the class progresses to the next lesson. Use of this technique offers an opportunity for direct observation of the instruction given and its application by the student. When outside assignments are given, they can be devoted to textbook study and review of problems completed.

FACILITATING THE UNDERSTANDING OF THE WORK SHEET

Try illustrating the adjustments of the work sheet by comparing with student experiences. Office supplies (when used as an asset) are to the proprietor of a business what groceries are to the homemaker. The groceries when purchased are assets to the family until the first meal is served, then they become an expense.

Compare the adjustment column of the work sheet to a book of original entry where entries must be made involving changes in accounts so that the ledger can be brought up to date. The result of the procedure, of course, is the adjusted trial balance. The breakdown of the adjusted trial balance in the remaining four columns of the work sheet should then involve a review of the chart of ledger accounts and the classification of accounts as to their permanent or temporary nature.

THE BUSINESS REPORT CARD

Some textbooks refer to the Income Statement of a business as a "report card" presented to the proprietor of a business at the close of a particular fiscal period. Capitalizing on this statement, every student has had the experience of analyzing his own report card and this same situation can be used in explaining the Income Statement. If a profit is reported, the proprietor has "passed;" if a loss is shown, he has "flunked" for the period.

A SYSTEM OF THEIR OWN

In beginning bookkeeping classes, it is sometimes effective to provide students with a series of transactions with the instructions that they keep a record, in their own way, to determine the profit or loss of the venture. After several weeks, students are given the same series of transactions with the instructions that they be recorded in a set of books using the double-entry principle. Finally, the first papers collected are returned and a comparison made between the results obtained.

INDIVIDUALIZING INSTRUCTION

Teaching on an individual basis enables the average student to progress more rapidly and affords the instructor additional time to spend with the slow student. The personal contact of individualized instruction gives the instructor an opportunity to become better acquainted with the student, to help him develop proper attitudes toward his work, and to adjust to procedures that are demanded by business.

MORE ATTENTION TO THE SUBJECT OF TAXES

In this complex world of ours, we in business education often permit our students to graduate from school without a sufficient understanding of the various taxes and tax benefits typically encountered by most citizens. Instructors should be sure that the business curriculum gives adequate attention to this important topic. In the private business schools, this may involve the initiation of a course devoted exclusively to the topic.

The subject of taxation and tax benefits should include treatment of property taxes, Federal income taxes for the individual, Federal Old-Age and Survivors Insurance, Federal and State Unemployment Insurance, New York State Disability Benefits, State income taxes, sales taxes, and excise taxes. Of course, there are other taxes which might be included, but the instructor should seek to concentrate on those tax laws and benefits common to most individuals.

Students must fully appreciate and understand the benefits of taxation. Many of our citizens, for example, do not understand their rights or benefits under the Federal Old-Age and Survivors Insurance law and, as a result, lose benefits to which they are entitled. Far too many citizens also fear the thought of preparing a Federal or State income tax return. Perhaps business educators are to blame, in part, for they may fail to include enough instruction on the subject of taxation in the business curriculum.

The treatment of this topic must be both theoretical and functional, with most of the emphasis being placed on practical applications. The rules and regulations of the tax laws should be discussed fully and then applied to simple commonly encountered problems. Students

should be given the opportunity to work on the various tax forms which they will meet in business and personal life.

Give students an opportunity to prepare a tax form or solve a tax problem without any assistance. This will provide them the opportunity to apply the law as they understand it and to express, in writing, their interpretation of how the laws should be applied. After the form is completed or problem solved, the results may be compared with those arrived at by other members of the class. Students will then be able to observe where errors were made and take precautions to avoid such errors in other problems.

TIPS FOR TEACHING INCOME TAXES

It is stimulating to the beginning student if he is given an opportunity to actually visit the local office of the Director of Internal Revenue. On his visit he should attempt to obtain copies of tax forms that are used by individuals in the preparation of their tax returns. The booklet, Your Federal Income Tax, may also be purchased for a small fee.

In addition, the United States Treasury Department, Internal Revenue Service, will make available to schools a Teacher's Tax Kit and individual Student Handbooks for use in teaching the preparation of individual income taxes. Teachers will also want to have on hand one or more copies of Circular E, Employer's Tax Guide.

Because the student has personally visited the Office of Internal Revenue, his subsequent study of the subject seems to take on added meaning. It is possible that a group visit may also be arranged which will permit a more extensive explanation of the various activities of the office.

GENERAL TEACHING SUGGESTIONS

IN

BUSINESS EDUCATION

QUESTION AND ANSWER BOARD

For short reviews and a bit of fun in the teaching of English grammar, filing, or typewriting theory, a question and answer board provides an interesting diversion. To make such a board, one needs only a board, two dry cell batteries, wire, a few nails, and a very elementary knowledge of electricity. After a demonstration--usually not needed in this scientific age--students are readily able to use the board. The board is so constructed that by answering a question correctly, a light on the board will light up. Students can be seen before class, at noon, and even after school making the board light up with the correct answers. This is a favorite with the boys.

SPELLING CONTEST

A spelling contest based upon a weekly class test will stimulate pupil interest in the improvement of spelling skill. Some teachers require only half of the homework assignment over the weekend from those students who are able to pass the spelling test with a grade of at least 90 per cent.

For variety, if practical, have students use the typewriter for the spelling tests. If typewriters are used, the teacher should read each word twice and after a word is pronounced the second time, the student should then type the word.

INVESTMENTS

Each student may be asked to select a stock, check into the background of the issuing company, follow the progress of the stock as it is reported in a daily newspaper, and then make a decision (with reasons) as to whether a purchase should be made.

PERSONALITY DEVELOPMENT--"A WAY OF LIFE"

Personality development is considered to be so important that it is frequently offered as a special course in many private business schools. In its application, however, personality development is fostered every minute of every day. In one of those schools where personality development is taught as a formal course, the student is given four criteria by which to measure himself in the light of a plus personality. He asks himself (1) Am I physically fit? (2) Am I mentally and morally fit? (3) Can I speak, read and write correctly? (4) Can I reason?

At every opportunity, the point is stressed that the ability to reason is the basis of a positive personality. The student is told that if reasoning is applied in his daily living, he need have little worry with respect to the other yardsticks presented. In fact (and this statement is often startling to him), he is further told that any defect which he may encounter in life he may well lay at his own door--for lack of ability to reason.

This philosophy is put into practice in every phase of the school's activities. If a student is late, he is not merely penalized for his tardiness; he is told why, the effect it has upon the program for the day, and what everyone stands to lose as a result. This same technique is followed when his work is substandard, if it does not come in on time, or if he fails to conduct himself in a proper manner.

The business of finding out where we err and how proper reasoning can help to set us straight gets to be a game. When a student states that he is applying "reasoning" to out-of-school and home problems, then there is reason to believe that he is being prepared both for a job in the business world as well as for a WAY OF LIFE.

TAPE YOUR INTERVIEWS

Taped recordings of interviews conducted by members of the class or by previous classes with men and women active in the field of study serve as a valuable aid in many business classes. Such interviews might have been obtained with a local stock broker, corporation president or other officer, market research specialist, banker, director of an employment agency, management consultant, or other persons in the business community. In one instance, these recordings were the product of a weekly radio program created, directed and moderated by a faculty member over a local radio station.

DISCUSSION OF CURRENT EVENTS

A part of the class period of certain of the business subjects can be spent profitably in the discussion of current world happenings and their effect upon the business world. This practice stimulates students to do more reading of current news and to try to understand the inter-relationship of current events and the climate of the business world.

FACTORS THAT INFLUENCE STUDENT ACHIEVEMENT

Factors constantly to be kept in mind by both teacher and student if a high standard of achievement in shorthand and typewriting is to be attained:

1. Realization on the part of each student that he must arrive at the classroom punctually, regularly, and prepared to participate fully in the daily lesson.

2. Prompt start of the lesson. A maximum amount of typewriting and shorthand writing should be done by students during every class period. There should be a minimum of time lost in lengthy teacher explanations.

3. Establishment of a spirit of friendly cooperation between students and teacher--both working at full capacity.

4. Insistence on the part of the teacher upon high standards of performance--work that will be acceptable to the most careful and scrupulous business executive.

5. Realization on the part of students that in skill subjects such as shorthand and typewriting, a great amount of practice is essential. This will require not only the completion of each day's homework but, in addition, much unassigned home practice.

TIPS FOR TEACHERS

DO -- learn the name of each student the first day of class, and address the student by name

--to aid in personalizing class instruction;

--to let the student know that the teacher is taking an immediate interest in him as a unique person!

DO -- remember the need for and use of many phrases of approval. Make use of an extensive series of synonyms for "good," "fine," and "excellent":

--to avoid student irritation at hearing one phrase repeated day after day;

--to insure that you as a teacher retain the power to motivate your students through phrases of approval that are sincerely given, rightfully earned, and proudly received!

EFFECTIVE TEACHING PRACTICES

Plant Visitations. Provide opportunities for your classes to visit one or more local business organizations. If the class is studying stenography, try to arrange a visit to the stenographic pool. Afford students the opportunities to see as many phases of a stenographer's work as an organization of this size requires.

Visiting Lecturers. Supplement your own knowledge of the subject by bringing in an occasional "outside expert" to lecture on his field of specialization. Your students, you as a teacher, and the school will all benefit.

Records and Tapes. Make use of records and tapes to supplement your classroom instruction and permit the student to listen a second time to any points of information you wish to stress. In shorthand classes, recorded dictation will make it possible for the teacher to divide the class into groups and provide dictation for each group of varying difficulty and rates of speed. Recorded dictation will also supplement the classroom dictation by making it possible for students to have carefully prepared dictation that can be used at home.

The Overhead Projector. The overhead projector is a valuable teaching aid in almost any classroom, but it is especially useful to the teacher of bookkeeping and accounting. Business forms, problems, and solutions to problems can be placed before the class in a minimum of time; the chalkboard can then be kept free to supplement the projected material. Problems partially completed in one class period can also be placed before the class the next day with a minimum of effort on the part of the teacher.

Preparation of a Yearbook. As part of the classroom activities in Distribution, students develop a school yearbook. The class assists in the layout of the book and with the writing of copy in addition to being responsible for obtaining ads and sponsors to help finance the cost of the publication.

Word for the Day. A new word is posted each day either in one of the school corridors or in one of the business classrooms. In the English classes, the instructors reinforce the student's learning of the new word by asking the class its spelling and use.

INDIVIDUALIZING INSTRUCTION

In a system of individualized instruction as occurs in some private business schools, students are given the opportunity to progress in a subject entirely at their own rate. The teacher, furthermore, is readily able to gauge the learning strengths and weaknesses of each student. The teacher is frequently able to anticipate the errors a particular student is apt to make and help to prevent the errors by warning him in advance. The personal attention that the teacher affords each student also puts the student at ease so that problems can be discussed readily and without embarrassment.

Since it is recognized that there are marked differences in learning rates from one student to another, methods of instruction which permit individual student progress should be used more often in our secondary schools.

ESTABLISHING GOOD STUDENT-TEACHER RAPPORT

The teacher who has the good will of her students will usually get their best effort. It is important that a teacher show genuine and sympathetic interest in the problems of each student. A teacher will be most effective if she will make a practice of learning as much as she can about the problems of each of her students. She should encourage students to bring problems to her. The teacher who has the good will of her students will find that they will be reluctant to "let her down" by putting forth any less than their optimum effort.

TALK WITH CHALK

Using the chalkboard at every opportunity will help students to learn. Whenever possible, illustrate the point that you are trying to

impart by using the chalkboard. Students will benefit from the use of multiple-sense appeals. Hearing and seeing a point illustrated as it is being made by the teacher will frequently facilitate learning.

THE ANECDOTAL APPROACH

Vitalize your teaching by incorporating interesting, but relevant, stories into your classroom presentations. This teaching technique is particularly valuable in classes such as business law. Students retain subject matter longer when served in palatable morsels!

DEVELOP MODEL SOLUTIONS

Model solutions to problems which contain detailed marginal notations or explanations will enable a student who is encountering learning difficulty or the student who has been absent from class to work independently of the teacher and check his own solution. A carefully annotated model solution is equivalent to the help a student might derive from a private tutor.

BRIDGING THE GAP

For students of business, the classroom is the business office; and all training in business subjects should be provided with that principle in mind. Making the classroom closely relate to the atmosphere found in a business office will help business students bridge the gap between the school and the job.

The student must get the feeling that the classroom is a business. This must be instilled. It can be accomplished over a period of time with the patient effort on the part of the teacher and without the awareness on the part of the student that he is being indoctrinated.

To accomplish this objective, attention should be given to:

1. Developing self-discipline

   Most students, if kept busy, realize that they have a job to do and willingly accept the responsibility. The problem of discipline for the teacher is over. Self-discipline will result, therefore, if the teacher is able to provide each member of the class with meaningful tasks--learning experiences that the student feels he will profit by.

2. Courtesy

   Courtesy among members of a class is greatly stimulated by teacher example. The teacher must try to instill in the class the principle that courtesy is an expression of respect. Courtesy in business requires attention to good manners; courtesy also involves the knack of being pleasant and aware of opportunities to be of help to fellow employees.

3. Honesty

Few students would deny that lying is dishonest, that lost property should be returned, or that stealing is wrong. But it is the more subtle evidences of honesty that the student and office worker fail to recognize. It is sometimes difficult for the student to realize that he is being dishonest when he copies work from a fellow student, when he fails to report all of his homework errors, or when he makes indiscriminate personal use of school supplies.

4. Teacher-student relations

The relationship between student and teacher should approximate that of employer and employee or employee and supervisor. There must exist a feeling of mutual respect and understanding of the problems of the other. There must also be an atmosphere of friendly cooperation but respect.

5. Use of reference aids

Students must also become accustomed to using common general reference aids that will facilitate their work. Employers place a great deal of reliance on the ability of stenographers and typists to spell, to punctuate properly, and to supply a variety of information that can be found in good general reference books. Students should be given many opportunities to demonstrate their ability to use effectively such references as an abridged or unabridged dictionary, encyclopedia, Postal Manual, yearbooks, travel guides, books of quotations, directories and the like.

6. Use of realistic classroom materials

Wherever possible, supplement textbook materials with work assignments garnered from business. For the stenographer and typist, a variety of tasks are provided by business organizations through the FBE BULLETIN. Most business teachers are familiar with the materials entitled "A Typist's Day in the Office" and "A Secretary's Day in the Office" provided through the FBE BULLETIN to classroom teachers.

Dictation copy and copy for typewriting practice can also be taken from current periodicals and newspapers. This technique has the advantage of helping students to keep current with important happenings taking place daily in the world of business.

TEACHER FOR THE DAY

Permit selected students to "teach" for five or ten minutes on Friday of each week. This lesson will ordinarily be a review of material covered during the past week. The student should be assisted by the teacher in preparing the lesson and should be encouraged to make use of charts or other visual materials that will help to make the presentation effective.

STUDENT SPEAKS REPORT

Each week the teacher submits titles or topics to be used by a student as the basis for an oral and written report. The student volunteers for the task rather than being drafted by the teacher. Some of the topics could be: The Stock Market, Federal Reserve System, Bonds, Banks and How They Operate, Loans and Mortgages, Consumer Credit.

This is an opportunity for a student to demonstrate his initiative. Because the assignment is taken voluntarily, the teacher will probably want to provide "bonus credit" for a task well done. The finished report should be typed and given to the teacher after the student has had an opportunity to report orally before the class.

ABSTRACT - Curriculum materials for teacher use in planning a 1-year high school Family Relations Course were developed by local home economics teachers and supervisors. The course is organized on a sequential basis, with each unit proceeding from the concepts, generalizations and understandings developed in earlier units. An introductory section discusses teaching methods. Each of the eleven units contains an overview, basic understandings, suggested experiences and activities, summary, evaluation and references. Subject matter covers: contemporary families, relationship with parents, maturation, marriage, problem solving, family finance, children, the elderly, community, and the projected family. Forms, charts, questionnaires, graphs, and a bibliography of professional resources and periodicals are included in the appendix. (FP)

FOREWORD

September, 1965 - an era of space ships, complicated computations and plans for landing on the moon - cries aloud for an island of refuge from a pace more rapid and tense than ever the world has seen. Serious reflection suggests that the family unit can be our island of refuge and may meet our needs more basically than at any previous time. Creative family living which provides for the flowering of individual personality and, also, for harmonious and intimate group life, is essential to our sanity and national health. Accomplishing creative family living, however, is neither automatic nor mechanistic.

Experiences which guide us in getting along with and understanding ourselves and others are not easy to attain. The child learns from the time he arrives in the world. The home has the first fundamental responsibility for education in family living. The church and community also contribute. The school has a responsibility.

Students, by the time they reach their senior year in high school, have many questions about themselves, their relationships with their peers, moral standards and marriage. Frequently they are confused in their thinking about values and goals. They need opportunities to consider, in an objective atmosphere, some of their concerns with their peers and with well-informed, emotionally stable adults who may guide their reflections.

In Kansas City the schools have accepted responsibility for guiding youth in the area of family life education. The securing of pertinent information, the development of wholesome attitudes toward marriage and family life and the formulation of workable concepts and generalizations are emphasized in the course for seniors, entitled Family Relations.

This curriculum guide has been outlined for the use of administrators, counselors and family living teachers.

Grateful appreciation is expressed to all who have made the guide possible:

- The family living teachers have contributed generously of their time and from their rich experiences with many students. Without their assistance the guide would be meager, indeed.

- Miss Rosemary Beymer, Director, Art Education, Kansas City, Missouri, Public Schools, and her assistants have designed the attractive cover of the guide.

- Mr. Don Smith, Director, Audio-Visual Education, Kansas City, Missouri, Public Schools has assisted in bringing the Audio-Visual Instructional materials up-to-date.

- Dr. Gordon E. Wesner, Assistant Director, Secondary Curriculum, Kansas City, Missouri, Public Schools participated in the writing of the guide. Every page reflects his breadth of vision and extensive knowledge. His enthusiasm was a constant source of encouragement.

It is our hope that this guide will provide a functional blueprint for achieving the goals and purposes set forth.

INTRODUCTION

Overview

Creative family life in which the principles of sound mental, emotional and spiritual health are basic is a precious possession. It is in the family that our foundations for living are laid. The infant comes to his home with potentialities but no attitudes or skills and few patterns of behavior. His day-by-day experiences play a large part in his growth. How his potentialities develop, what his attitudes are and how he behaves will depend first of all upon his mother and father, brothers, sisters and other relatives. As he grows older, the neighborhood, community, national and world factors will influence him. The family, however, is first.

There are no well-defined rules for building this creative type of family life mentioned above. There is, indeed, no one pattern. As we look around, we realize that there are many patterns and that diversity is to be prized. To encourage young people to give thoughtful attention to the essential elements involved in creative living in the family and how these elements may be evolved is, in broad terms, the goal for this high school course in marriage and family living for senior boys and girls.

General Objectives

Throughout the course, emphasis is given to guiding students to:

- Develop constructive attitudes concerning oneself, the family, family relationships and family-community relationships
- Gain useful knowledge, understanding and concepts about growth, relationships, values and value systems, change, creativeness and family living in general
- Learn to live more successfully personally and in their parental families
- Acquire a background, supplemental to that which they already have, which will be of value to them in establishing their own homes and families
- Believe in the dignity of man, the worth of the individual, the need for individual fulfillment on a moral basis and the need for working together in the family unit toward common goals.

Educational Planning by the Administrators and Counselors

Increasingly it is being recognized that the whole area of family life education is a real necessity as general education for our young people who are the future founders of families.

All about us we are conscious of:

- Early marriage
- Increasing divorce rate
- Spread of venereal disease among youth
- Downgrading of moral standards and values
- Increasing numbers of children in conflict.

These are factors which interfere with our national welfare and advancement. The content of the course, entitled Family Relations, contributes richly toward self understanding, appreciation of today's family and its place in our nation. Inasmuch as this is true, it would seem wise as we plan programs and guide boys' and girls' educational progress through the secondary school, that as many students as possible, have experience in family life education while they are in the high school. This course is useful to all - those with high ability as well as those with average or lesser abilities.

Family Relations is a developmental course which is organized on a sequential basis. Each unit proceeds from the concepts, generalizations and understandings developed in earlier units.

During the first semester, the foundation is laid. Basic knowledge is presented, concepts and primary generalizations are developed early in the school year. The emphasis is on the student developing understanding of himself, his relationships with his peers and his place in the parental family.

During the second semester, the emphasis is on the student's future family - its founding, its problems and adjustments in a rapidly changing world.

Understandings developed early in the year are essential to learnings later in the year. The students, therefore, must be in the course from its beginning in order to benefit adequately from class instruction and in order not to interfere with the progress of the other boys and girls.

It is hoped that school Administrators will find this Family Relations curriculum guide of assistance as they plan the educational program and determine the appropriate educational climate of the secondary school. The guide should give administrators ideas of how this course attempts to meet students' future needs in this broad and basic area of general education.

The Counselor understands the needs, interests and aptitudes of each individual student. Counselors, therefore, are encouraged to read and study the curriculum guide in order to recognize the importance of its content for completing the secondary education of boys and girls. Since this area is recognized to be such a vital part of general education, every attempt should be made to provide experience for each outgoing senior. Students from broken homes, especially, should be encouraged to enroll.

Accomplishing Goals - To the teachers

It is not too difficult to teach students certain subject-matter facts pertaining to marriage and family living. While factual information is helpful and necessary, attitudes, convictions, insight into problems, vision, basic understandings, concepts and emotional maturity are something quite different and infinitely more important. Our goals in this course must be, therefore, of two-fold nature: informational and attitudinal. They must involve feelings, understandings and motivations toward helpful ways of living. The effectiveness of this course will depend upon the quality of the person who teaches it, the techniques he uses and the involvement of the students.

The teacher is of first importance in accomplishing goals. The effective teacher of family living will:

- Be well-adjusted and mature emotionally
- Like and get along well with other people
- Be a person for whom the students have respect and in whom they trust
- Have a psychological - sociological orientation in his academic preparation
- Appreciate the values of home and family in encouraging optimum personality development
- Exercise good judgment in selection of subject matter, student activities and in class discussion
- Believe that there are many right patterns of family living and that no two families need to have the same pattern.

It is especially important, in a course concerned with human relationships, for the teacher to build a teacher-student relationship in which there is mutual respect and liking. The teacher's feeling about each student is fundamental. It needs to be remembered that every student, regardless of his degree of intellectual ability, is a potential homemaker and family member of the future.

The adequate teacher in family life education will not condemn or criticize a parent or parents in general. Also, he will not condemn students for their points-of-view on behavior. The teacher's task is to lead boys and girls to examine, analyze and criticize for themselves their goals,

ideas and behavior but he does not condemn them when they differ from him. This does not mean, of course, that teachers should not hold to high-quality standards or guide young people to determine their behavior on a moral basis.

The teacher, to be effective, needs to make himself available for individual conferences. Counseling, to be of real value, requires special skills, which means that teachers must prepare themselves for their counseling role. Reading, talking with others who have acquired a wholesome counseling philsophy and useful skills, enrolling in academic courses on counseling are some of the ways of developing competence. Advice-giving is natural to many people. Counseling and advice-giving are not synonymous.

Student participation is essential in promoting growth. Behavior and attitude changes are brought about by doing rather than by passive listening. Many different techniques will be used to fulfill individual needs. Some students learn by one method, some by another. Some devices are more suited to one area of discussion and some to another. If teaching is to be successful, techniques must be developed which will lead students to think through their interests and concerns, to analyze, ask why, develop ideas and make decisions.

The activities and experiences throughout the guide are suggestions only. Some will be suitable at one time and some at another time. The teacher may create more meaningful activities than any of those listed. These suggestions are not meant to be restrictive and certainly not stifling. They are a point of departure.

Since there are other courses in the high school curriculum in which there could be duplication of material involved (e.g. psychology, human science, home economics), it is wise for the teachers of these courses to plan together for a correlated approach. In this way various areas can be covered more thoroughly and from different points of view. The family living teacher should be the one to take the initiative in this matter.

The remainder of this Introduction is devoted to a short discussion of concepts, basic understandings, techniques and devices for stimulating learning. It is suggested that it be studied frequently.

Concepts and Basic Understandings

It is hoped that family living teachers will work toward encouraging students to understand concepts and basic understandings involved thus enabling our young people to function more adequately as individuals and as family members.

Before attempting to guide students in the development of their own concepts and generalizations, the teacher needs to have formulated some basic ideas along these lines. Following are a few hints that may be useful:

A concept is a mental image, a symbol or statement.

- A concept is a general notion about something. It grows as one learns more about it.
- One concept rests upon another. The meaning of a concept develops slowly out of many experiences.
- It is the teacher's job to provide as many experiences as possible which are vital to the area under consideration in order that the concept produced by the student may be as accurate and as meaningful as possible.
- Example - A certain mental image is brought forth when one sees the word "family". A two-year-old's image differs from a thirty-year-old's image.
- Concepts develop from concrete to abstract
  vague to clear
  inaccurate to valid
  incomplete to broad as the learners have experiences to develop them.

A generalization is an underlying truth or basic principle or basic understanding.

- It has an element of universality and frequently expresses relationships.
- To be able to formulate a generalization or basic understanding, a learner must be able to perceive two or more concepts and then to understand the relationship between them.
- Examples:

  Each stage of the family life cycle requires admustments.

  Marriage is more likely to succeed when there is similarity of backgrounds of marriage partners.

  Credit rating is established by one's performance in fulfilling credit contracts.

  A child in our culture who develops a positive attitude about the importance of work is more apt to succeed as an adult.

We cannot give a concept or a generalization to a student, he must develop his own through various experiences.

Concepts and generalizations are the subject matter aspects of the curriculum. Their relationship to the curriculum might be illustrated thus:

In a meaningful curriculum, according to Helen Westlake*, four questions must be asked:

- What is to be done
- What subject matter is to be used
- What methods and organization are to be employed
- How are the results to be appraised?

*Westlake, H. - "Teaching for Concepts and Generalizations in H.E. Education", American Vocational Journal, Dec. 1964, p. 17

In this curriculum guide some of the generalizations that seem to be outstanding are listed on the left hand side of the page as basic understandings. Others may need to be included according to the insight of the teacher and the students.

- Concepts are not identified. It is assumed the teacher will identify the concepts inherent within the basic understandings or generalizations.
- "Learning experiences should be planned which will enable students to locate, interpret, and evaluate supporting facts, participate in a variety of related experiences and finally apply learnings to new situations." *
- On the right hand side of the page, some suggested activities or learning experiences are outlined. The teacher and the class may devise other more meaningful activities which will help the students develop for themselves the basic understandings involved.

Techniques and Devices to Stimulate Learning

	Some Suggestions For Use
Reading	Reading is still the most important source of obtaining information for the high school student. It is the teacher's responsibility to provide reading material of various levels of difficulty. The use of the Public Library is imperative. Arrangements may be made with the librarian for books to be used in relation to the different units. Use some of the many books of fiction presenting family life situations.
File of Reading Cards	A file of reading cards (5 x 8) on which articles read may be summarized may be stimulating and useful.
Films	A film should be used only when it illustrates, clarifies or develops ideas, principles or facts that are being taught. It is a device to promote learning, not an end in itself. In almost every unit valuable films are available.

*Taken from "Thoughts For An Educator", by Dr. Barbara Osborn - Penney's Fashions and Fabrics, Spring/Summer, 1964, p. 12

Techniques	Some Suggestions For Use
	The teacher should preview each film and develop a film guide for the students which will give them some specific things to observe. Following the film there must be consideration, in some manner, of the principles, ideas and facts illustrated and their meaning or application.
Interview	Information may be secured and facts learned by having students interview other students in the school, faculty members or persons from the community. Adequate preparation before interviewing is essential not only to secure the desired information but also from a public relations standpoint. Adequate preparation includes having the questions about which information is to be secured clearly defined and understood by the student. An interview form or schedule of questions to be asked is useful. This should be compiled by the student and approved by the teacher especially if it is to be used with faculty or community persons. Before any interviewing is done, the teacher should discuss with the students the procedure for securing an interview, emphasizing the importance of explaining who you are, why you want an interview, what the interview is to be about and making a definite appointment. If the interview is to be with a community person, the first contact probably should be by a letter of explanation. This could be followed by a telephone call asking for an appointment. An interview with any adult should be followed with a letter expressing appreciation for the time and information given.

Techniques	Some Suggestions For Use
	Teachers should emphasize with students that information given must be treated with respect and in a confidential manner.
Guest speakers or resource persons	Resource persons should be chosen for their ability to give accurate information or to stimulate thinking.
	Persons invited need to be carefully briefed in regard to the exact subject matter to be included, time allotment, nature of the question and answer period, the hour to arrive and the place to report.
	Arrangements should be made for courteous reception in the school office and in the classroom. The principal should be informed.
	A note of appreciation is common courtesy and is a worthwhile student activity.
Panel Discussions	Panel discussions are often a helpful way to bring information to the class and to stimulate thinking.
	Panels may be composed of students, parents, community persons or any combination of these persons. When students are used in discussion, have them prepare themselves by reading or research.
	Assignments should be definite and limited. Avoid covering too large an area at one time.
Buzz Sessions	Sometimes discussion in small groups is valuable.
	Buzz groups are usually composed of three to five persons. Each group should have a leader who can be chosen by some objective method such as the one whose last name begins with "A" or closest to "A".
	Assignments need to be definite. Sometimes it is helpful to assign different questions to each small group.

356

Techniques	Some Suggestions For Use
	Discussion periods should last about ten minutes. Follow with reports from each group to the class as a whole (made by each leader) and general discussion.
Brainstorming	In brainstorming a word or concept is set forth and each student is asked to write down quickly all the ideas it suggests to him. Allow a few minutes and follow with discussion.
Newspaper and Magazine Articles	Advertisements, newspaper and magazine articles referring to home, family life and personal development are often stimulating and help to keep course material interesting and up-to-date. These may be used to start a discussion and evaluation by considering fundamental principles involved, fallacies, advantages and disadvantages of the ideas expressed or facts stressed.
Charts, Notebooks, Posters and Projects	Students often are interested in developing charts, notebooks, bulletin boards, posters and other projects which represent certain concepts or display definite information. Most projects of this type involve facts and should be based on accurate information. This means that students must secure their data from reliable sources. Through these projects, boys and girls may learn that there are reliable and unreliable sources of information and that we must learn to discriminate. A notebook, to be valuable, must include some analysis, critical evaluation or pertinent remarks by the students. Merely pasting articles in a book, or copying materials is useless.

006357

Techniques	Some Suggestions For Use
Case Material	Case material may be secured from various books and articles, or it may be developed by the teacher or one of the more able students. A simple example would be "Harry is a boy with a fine physique. He is much interested in competitive sports and longs to be a member of one of the school teams. He is prevented from participation by extreme shortsightedness which requires him to wear thick glasses. How can he learn to live with his handicap?"
Skits or Role Playing	There are a number of short plays available which have been prepared with definite teaching purposes in mind. Some of the best of these are by the Theatre Guild and are known as "Mental Health Plays". More detailed information may be secured from the Director of Family Life Education. Such plays may be performed by the students and followed by discussion. Frequently it is helpful to have developed beforehand some very definite questions for the students to discuss. Simple plays may be developed by students with talent for this type of thing. Frequently, role-playing may be done on an unrehearsed basis, illustrating an idea. For example, four students could role-play a girl introducing her boy friend to her mother and father with several methods of approach. Several students could demonstrate how and how not to hold a telephone conversation with a friend. Useful situations are endless. Skits and role-playing should always be followed by discussion. They are not planned for amusement purposes only.
Surveys	Students, singly or in committees, may make surveys to discover certain definite facts. A review of printed materials in regard to a definite topic may be made.

Techniques	Some Suggestions For Use
	A survey may be an examination of conditions in a community of a study of peoples' points of view. Discussion and evaluation are an important part of a survey project.
Themes	Sometimes students learn by developing a theme on such a vital topic as: - How teen-agers can build better relations with their parents - What are some of the most important qualities needed for a successful marriage. Consult with English teachers concerning good standards for theme writing.
Pictures	May be used to stimulate discussion. Show a picture depicting family living situations and then ask such thought-provoking questions as: - What do you think is happening - What might have caused this situation - What do you think will follow?
Observation	Observation of children, adults and relationships may be helpful. Observation may be in a well-organized situation such as a school room or on an informal basis such as in the neighborhood, in the grocery store or bus. Many kinds of assignments may be made which will help students to understand growth behavior and relationships, for example: - Have the students observe a preschool child in a grocery store -- his mother's reactions -- discuss some possible reasons why they behave as they do. - Have students write down conversations between children of younger ages -- discuss and evaluate the meaning.

Techniques	Some Suggestions For Use
Evaluating Devices, Tests, Rating Sheets, Others	Essay and objective tests are useful to check information. Personality rating sheets and other check lists may be used to help students start to evaluate in various areas. These devices require thoughtful preparation by the teacher. They can be administered at various times throughout the year to show growth or change and may be used year after year with revision and refinement.
Statements from Books, Newspapers or Other Writings	Challenge and analyze these statements. Who said it? On what basis? Do we believe everything that is said or written?

The teacher in using any technique should ask:

- What do I expect to accomplish with this technique
- Why am I using this particular technique
- What will the students learn
- What subject matter will be presented?

Using This Guide

This guide on Family Relations for the Twelfth Grade has been compiled on the basis of knowledge gained by the teachers who have taught these classes over a period of many years, the Assistant Director of Secondary Curriculum and the Director of the Department of Family Life Education. The willingness, especially on the part of the teachers, to share experiences, joys and tribulations has made it possible to enrich the content in ways not originally contemplated.

As stated previously, this is a guide, not a rigid curriculum. Its purpose is to encourage teachers rather than to restrict, inhibit or leave them with feelings of frustrations. Many suggestions have been made. No teacher will include them all in his teaching. Additional ideas, activities and techniques suitable for particular needs will be developed by creative teachers who wish to make their family living classes a rich experience for their students. Some teachers may prefer to combine parts of one unit with some other unit. It is expected, however, that teachers in Kansas City will present the essentials of each unit in some way and will abide by the general underlying philosophy of the family living course as a whole.

The time suggested for each unit is the result of the combined judgment of the curriculum production committee. Naturally adjustments will have to be made to meet local needs. However, attention to the time suggested can help to insure each student the opportunity to benefit from the total course and prevent gaps in his experience.

It is imperative that each teacher exercise good judgment in his presentation of materials and in his use of activities and teaching methods in order that students may be given the opportunity to learn and grow in accordance with their age and needs. Ideas and methods for which students lack readiness and experience can be disturbing and harmful.

It is suggested that each year the teacher note in the guide, unit by unit, suggestions which will make his teaching more meaningful the following year.

KEYS TO GOOD TEACHING

Ask rather than answer.

Teach rather than preach.

Observe rather than look.

Interpret rather than judge.

Seek rather than accept.

Particularize rather than generalize.

Elizabeth Force

Teachers, help your students to spend themselves well.

UNIT I - The 20th Century Family in the United States

Suggested Time - 2 weeks

Overview

In this rapidly changing technological age, the family is our most precious possession since it is in this group that our foundations for living are built. The infant comes to his home with potentialities but no attitudes or skills, and few patterns of behavior. At every age, from infancy through the entire life cycle, relationships with others determine to a large degree the development of one's potentialities, attitudes and behavior patterns. These relationships begin in the family. They are nurtured in the family. They are enlarged in the community.

Children today grow up in a social situation in which changes in values, beliefs, expectations and conduct are taking place so rapidly that parents often are unable to understand how and why adolescents think and behave as they do. Family needs and interests frequently are sacrificed to social, economic and political situations within today's world. If satisfactory families are to continue as the fundamental units of society, young people must be guided in making lifetime decisions, with stress on the need for maturity and readiness to meet adult responsibilities. There must be emphasis on developing a value system which will encourage each person to function adequately as a moral being, living a creative life satisfying to himself and acceptable to society. There is no one recipe for building worthwhile, constructive family life. There is, indeed, no one pattern. There are many patterns, diversity or uniqueness is to be prized rather than discouraged. Specific details of pattern may vary, but fundamentally, constructive family life is concerned with enabling each family member to grow and develop in ways which permit him to: feel comfortable about himself, feel right about other people, and be able to meet the demands of life because he has matured and developed his capacities and abilities.

General goals or objectives of the course may be stated as guiding students to:

- Develop constructive attitudes and acquire useful knowledge and understandings about themselves, their own sex and the opposite sex, their peers and those older and younger than themselves

- Critically evaluate current behavior patterns, moral standards, cultural group values, individual value systems and present day customs as a background for formulating their own personal philosophies of living, including their own value systems, later to be used in rearing the next generation

ca362

- Become acquainted with the concept of family growth and recognize the various stages in the family developmental cycle

- Acquire useful understandings in regard to values in constructive family living, as well as recognizing the necessity for constant change and how this can be a force for creativeness in family life, a quality characteristic of strong families

- Realize, at least to a degree, the impact which the community has on the home and to obtain knowledge of the resources available to families today and how these resources may be used effectively

- Develop understanding about the family's responsibility to the community

- Gain knowledge, attitudes and understandings which will be useful to them in establishing their own family units and in developing a democratic way of living

- Believe in the dignity of man, the worth of the individual, the need for individual fulfillment on a moral basis, the value of diversity in abilities and efforts and the need for working together in the family unit toward common goals.

Basic Understandings	Suggested Experiences & Activities
Most of their lives, people live in the small group situation of the family; hence, it is important to have a working knowledge of family organization, function and value.	This course may be initiated by asking the students to discuss such questions as: - Why have you enrolled in this course - What do you expect to study or learn - How would you define a family, a happy family? Is the term "happy" a good one or is there a more appropriate term? - How do you distinguish between a house and a home? Reference: - Hoeflin, R. - Essentials of Family Living, p. 2-19 The overall objectives of the course should be discussed, making clear that this is a course devoted to all aspects of family life.

FA 63

Basic Understandings	Suggested Experiences & Activities
	Have students make a list of the functions of the family today and yesterday - compare and point out the changes that have occurred. Discuss the meaning of these changes to each member of the family from the youngest child to the grandparents, as well as to other members of the larger family group.
As one becomes acquainted with many families, it is recognized that there are many ways of living together as a family. Uniqueness in families may be a great asset.	Have the students discuss the meaning of family pattern, family traditions, democratic family life, etc. Outline different, acceptable patterns which might be developed in a family. Compare in general our ways of family living with those of other cultures. Seek to discover some common factors in American family life. Consider how families of different origins may live together creatively in a community.
There is a growth pattern which families follow known as the family life cycle. This is a frame of reference for understanding family life.	Discuss the meaning of "family life cycle". Outline and discuss the stages in the family life cycle. Use a chart depicting the eight stages in the family life cycle. References: - Duvall, E. M. - Family Development, p. 7, 9, 13 - Hoeflin, R. M. - Essentials of Family Living, p. 88-102 - Appendix B Identify with the students the stages in the family "life cycle" in which their families are. This may be done by having each student develop a chart depicting his own family's growth. Develop an understanding that stages may overlap to a degree.

Basic Understandings	Suggested Experiences & Activities
	Help the students to see that the family life cycle is a dynamic, growing concept, with the family passing from one stage to the next.
At each stage in the family life cycle, there are family developmental tasks to be accomplished if the family is to function competently.	Present the meaning of developmental tasks as applied to the family. Reference: - Duvall, E.M. - Family Development, p. 27-51 Consider how these tasks, if accomplished, help the family to grow as a functioning unit. Identify the developmental tasks of the family in which there are persons ages 14 to 18. Reference: - Duvall, E.M. - Family Development, p. 288-331
For each member of the family there are individual developmental tasks to be accomplished.	Introduce the concept of individual developmental tasks as they relate to family developmental tasks. Have the students read and discuss briefly the developmental tasks to be accomplished during the teen years. This discussion should lead to the introduction of the next unit on the young person and his parental family and the study of personality development.

Vocabulary:

- attitudes
- behavior pattern
- competent
- cultural group
- developmental tasks
- evaluate

Basic Understandings	Suggested Experiences & Activities
family family development family life cycle matriarchal maturity patriarchal personality potentialities readiness role technological traditions uniqueness values	

Culmination and Evaluation

Several persons representing families at different developmental stages could be invited to discuss with the class their ideas of the characteristics of a successful family. Plan with the Parent Education Chairman of the PTA.

Have each student consider carefully:

- "What did we learn in this unit?"
- "What does it mean to me?"
- "Where can I use it again?"

The teacher may say to the students, "When we started this unit each of us had some ideas about family living. During these few weeks we have considered some different ideas. How has our discussion changed your thinking? Can you formulate any brief generalizations that may have come from our class work?"

Take part of a period to discuss the learning that has occurred.

UNIT II - You and Your Parental Family

Suggested Time - 4 weeks

Overview

Developing personal adequacy and learning to live congenially and competently in one's own family are two of the major tasks which young people face in our culture. Therefore, early in a course in family relations it is appropriate to include a unit which considers personal development of the student and his place in his parental family.

Specific Objectives

This unit seeks to increase the young person's understanding of:

- Developmental tasks to be accomplished during the teen years
- Growth toward maturity, contributing factors
- Principles of good mental health
- His place in the parental family
- Developmental tasks of parents and the problems which they encounter
- Interpersonal competence with parents, brothers, sisters and other relatives in the family
- Basic needs of various family members, including his own.

Basic Understandings	Suggested Experiences & Activities
Personality development is a lifelong process with definite developmental tasks to be accomplished at each age level.	Discuss the meaning of the concepts involved in this basic understanding. References: - Duvall, E. M. - Family Living, p. 3-28 - Landis, J. & M. - Personal Adjustment Marriage and Family Living, p. 3-24 Have students outline the main developmental tasks of the teen years. Discuss.

Basic Understandings	Suggested Experiences & Activities
	Reference: - Duvall, E. M. - Family Living, p. 84-95
Accomplishment of these tasks requires developing degrees of maturity.	Discuss meaning of "maturity", "growth". Have students observe freshman boys and girls and compare their behavior, ideals, standards, values with those of senior year students. What has caused the change?
Teen-agers must grow toward individual maturity: - emotionally - socially - intellectually - spiritually - physically - sexually.	List and discuss the characteristics of each aspect of growth and point out their interrelationships. Invite a resource person such as the Director of the Kansas City Social Health Society to discuss sexual development. Have students cite examples of growth or lack of growth. Use personal growth rating charts - see Appendix B. Use charts showing the reproductive systems - see Appendix C.
Rate of growth and capabilities vary among people.	Read Menninger, Wm. C. - Understanding Ourselves. Discuss indications of mature behavior. Have each student list characteristics of a mature 18-year-old. Each student could rate himself in regard to his maturity. Use SRA Youth Inventory - (a commercial device) - see references at end of unit.
Growth is related to both heredity and environment.	Through reading and discussion, seek to establish understanding that hereditary factors and environmental experiences influence growth and behavior.

ERIC 369

Basic Understandings	Suggested Experiences & Activities
	Reference: - Schienfeld, A. - The New You and Heredity Construct a family tree of three generations. Trace several hereditary characteristics which seem to appear. Have each student write his biography. The teacher should keep these for reference.
There are certain fundamental needs to be satisfied during the teen years. These are basic to good mental health and influence the accomplishment of teen-age developmental tasks.	Discuss and list the fundamental needs of the teen years. Reference: - Duvall, E. M. - Family Living, p. 52-84
When basic needs are not satisfied we resort to various behavior mechanisms.	Play and discuss the Menninger Records, Meet Your Mind. Make practical applications of the behavior illustrated in the records. Have students write a list of behavior mechanisms which they use from time to time. Discuss. Discuss mature and immature behavior.
Developing a philosophy of living is an important aspect of the maturation process Philosophy of living includes formulation of: - goals - values - convictions - standards for behavior	Explore the meaning of "philosophy of living". Invite a resource person, such as a minister, to talk about philosophy of living. Discuss application to the 17 or 18-year-old of: - Knowing oneself - Facing reality - Right and wrong - Honesty - Personal responsibility

Basic Understandings	Suggested Experiences & Activities
	- Freedom - Self-control - Facing problems - Healthy ways of solving problem situations. Discuss how we arrive at personal values, goals, etc. Have students write briefly about their chief joys, satisfactions, worries, fears and what they want to be. Follow with discussion avoiding use of identifying materials of any kind. Show a picture representing a problem situation. Have students discuss: - What is happening? - What may have caused the situation? - Suggest possible solutions. Reference: - Alberty, H. - Helping Teen-agers Explore Values
Young people need to grow and to adjust satisfactorily in their parental family units.	Analyze, explore and discuss the basic understanding listed opposite. References: - Duvall, E. M. - Family Living, p. 99-138 - Force, E. - Your Family Today and Tomorrow, p. 37-54
There are many reasons for parents behaving as they do.	Discuss the main areas in which problems and conflicts arise between youth and parents today in family living. Arrange a parent panel to discuss youth-parent conflicts. Show and discuss the film - Parents Are People Too.

Basic Understandings	Suggested Experiences & Activities
	Have students list what they expect of parents and what parents should expect of their young people.
Parents have developmental needs and tasks.	List developmental needs and tasks of parents. Discuss how parents might seek to satisfy these needs and achieve these tasks. References: - Duvall, E. M. - Family Development, p. 389-434 - Hoeflin, R. M. - Essentials of Family Living, p. 208-220
Brothers and sisters have developmental needs and tasks.	Discuss how you can relate to brothers and sisters as they seek to satisfy their needs and achieve their developmental tasks. Show and discuss the film - Sibling Rivalries and Parents. Reference: - Force, E. S. - Your Family Today and and Tomorrow, p. 55-73
In any adjusted family where there is respect for individual personality, there will be some conflict.	Discuss the meaning of "respect for individual personality", "conflict" and "the adjusted family". References: - Jenkins, G. G. & Newman, J. - How to Live With Parents (SRA Booklet) - Ullman, E. - Getting Along With Brothers and Sisters (SRA Booklet)
Some procedures for solving family conflict will be more constructive than others.	Illustrate constructive and destructive ways of solving conflict in the family. Have class discussion of such practical questions as: - What privileges do I need or want and am I ready for the responsibility implied?

Basic Understandings	Suggested Experiences & Activities
	- How can the family car be shared? - How may "apron strings" be cut? - To what extent should parents be included in planning and executing parties or social plans?
	Have students list three things they could do to make their family life more pleasant and satisfying. Keep a notebook record for one week. Evaluate project at the end of the week.
Young people have a responsibility for developing their ability to communicate with other family members.	Discuss the meaning of communication, empathy.
	List some ways in which family members communicate. Evaluate.
	How may teen-agers improve communications?

Vocabulary:

adequacy
attitude
behavior
behavior mechanism
communication
compensation
competition
conflict
constructive
convictions
culture
defense mechanism
development
emotional
empathy
environment
extrovert
goals
gossip
gratitude
growth
heredity
inferiority complex
intellectual
interpersonal competence
introvert

Basic Understandings	Suggested Experiences & Activities
maturation	
maturity	
patterns for problem solving	
personality	
philosophy	
physical	
puberty	
rationalize	
reality	
responsibility	
siblings	
social	
spiritual	
traits	
values	

Culmination and Evaluation

Have each student write a short description of the kind of person he would like to be - now and ten years from now.

Have some students develop pictorial representations of the meaning of maturity as related to personality development.

Have each student outline what he has learned about himself, including his strengths, weaknesses, values, goals.

Have each student list three problems he has faced recently, describing how he solved each problem or how he might have solved them if he had been more mature.

Have each student describe the most interesting personality he knows. Why is this person the most interesting?

Invite a resource person to talk about working toward achievement of personal goals.

Discuss concepts which have been clarified in this unit, generalizations which have been developed, and the practical value of these concepts and generalizations.

UNIT III - Growing Towards Maturity in Social Relationships

Suggested Time - 5 weeks

Overview

During the period of youth, establishing oneself with one's peer group is a major developmental task. Heterosexual relationships need to be established. Casual dating may lead to friendships which eventually lead to marriage. Social horizons widen and value patterns are established.

Specific Objectives

Goals in this unit are to enable young people to:

- Understand their own social growth and interests
- Develop acceptable social attitudes, behavior and skills which will be basic in their adult life
- Develop values and goals which will be useful to them now and later
- Be aware that their parents are responsibly concerned about their social growth and behavior.

Basic Understandings	Suggested Experiences and Activities
Social growth follows a pattern, the general sequence of which is similar for all young people. However, the rate of growth and specific details differ from person to person.	As a review of the social growth pattern presented in Unit II, plan panels on: - Environmental factors influencing social growth (home, school, community) - Mass media influences our social growth pattern (radio, television, advertising, newspapers, magazines) Reference: - Hoeflin, R. - Essentials of Family Living, p. 38-43
The teen years are a time for establishing many friendships - male and female.	Have the students bring articles, clippings, and advertisements relating to social acceptability. Critically

Basic Understandings	Suggested Experiences & Activities
To satisfy this interest, most youth strive to be acceptable to others.	evaluate these as a realistic basis for selection of friends. Discuss characteristics of a person who is apt to have friends. Socio-drama may be used to depict various stages of social maturity.
Dating requires social skills often spoken of as good manners.	Discuss the importance of manners. Study the skills needed in the following social situations: - Introductions - Eating - at home at school public place - Telephone calls - Entering a room - Going to a movie - Getting into a car - Timing the return home. Have the students develop standards for each of these occasions. Use role playing to demonstrate skills which are helpful in today's social life. Films: - Dating Do's and Don'ts - What About Dates References: - Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 45-57 - Duvall, E. M. - Family Living, p. 157-226 Develop, with the Home Economics Teacher, a cooperative project on setting a table, serving, correct table manners, how to invite a person to a social a affair, how to express your appreciation for entertainment, etc.

ETS 380

Basic Understandings	Suggested Experiences & Activities
	Consider the real meaning of social courtesy.
Dating is an important part of the social life of young people.	Read and discuss - Force, E. - "Climbing the Dating Ladder", Your Family Today and Tomorrow, p. 106-112. Outline the developmental growth involved.
There is a developmental growth pattern of affectional feelings and attitudes in boy and girl friendships. This results in stages in dating.	Arrange panel discussions on: - Why dating is important - Becoming more datable - Social skills helpful in dating situations.
	Have foreign exchange students discuss social life in other cultures.
	Suggest readings portraying social life in other cultures, for example: - The Good Earth - Pearl Buck - The Red Chair Waits - A. M. Hudgins.
	References: - Anderson, W. J. - Design For Family Living, p. 67-82 - Duvall, E. M. - The Art of Dating
There are some concerns which high school students have in common during the dating years e.g. - When to begin dating - Who asks for the date - How to accept or refuse graciously and courteously - Responsibility for planning - What to do - Where to go - Who pays the expenses - Time to be home - How often to date	Provide students, in committees or individually, opportunities to read about and discuss each of these common concerns. Urge them to understand reasons for acceptable behavior and for recognizing their responsibility. Have students develop a code of dating behavior which they think is reasonable for them to follow. Discuss the problem of maintaining one's standards when others do not agree. Invite appropriate resource persons, use films, etc. to bring information to students.

Basic Understandings	Suggested Experiences & Activities
- Blind dating - Pick-up dating - Use of automobile - Automobile manners - Parking and petting - Appropriate gifts - Adult supervision - Some do not date - Smoking - Use of alcohol and narcotics - Venereal disease	Show films: - How Much Affection - Alcoholism - Dating Topics for Older Teens - Innocent Party - The Invader
One's dating behavior is determined by one's values and standards and what he wants from life.	Have students list some do's and don'ts in behavior and why standards are important to us. References: - Alberty, H. - Helping Teen-agers Explore Values - Ann Landers' newspaper column Show film: - Going Steady Follow with further study and discussion as necessary. Have students discuss: - What is popularity - Is popularity enough - Force's statement, "Learn to read the price tag on popularity. Can you afford to pay the price?" - Your Family Today and Tomorrow, p. 100 - How are personal values and standards developed - Should one change one's standards to suit the crowd? Have students rate themselves as a date - Refer to Appendix B
Sexual maturity is a part of growth which the young person must face realistically in his relationships with others.	Set up situations in which the student may consider such questions as: - Should there be a double standard in behavior for boys and girls

Basic Understandings	Suggested Experiences & Activities
	- Our culture has decreed that intimate relations are to be reserved for marriage. Is this pattern of behavior acceptable to young people? - What standards of behavior in relation to sex, should be developed by young people? Encourage students to raise related questions which arise out of changing cultural patterns. Have students write questions to be discussed in class. At the close of the discussion formulate with the class three or more broad generalizations that seem to indicate the more desirable standards of behavior in relation to sexual attitudes. Reference: - Duvall, E. M. - Why Wait Till Marriage
There is a developmental growth pattern involved in love and affectional life - self love - parental love - family love for its members - friendship - both sexes same sex opposite sex - love for marriage partner - love of children - love of mankind.	Study and discuss the meaning of each stage in this developmental growth cycle. References: - Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 170-179 - Cavan, R. S. - The American Family, p. 364-383 Have students evaluate the type of love depicted in movies, in selected literature, etc. Discuss such questions as: - How do I know when it is real love - Is love a two-way street - How does love change - Why do some not date - How can social needs be met, if one does not date?

Basic Understandings

Suggested Experiences & Activities

Films:

- Is This Love
- How Do You Know It's Love

Discuss meaning of romance, infatuation, puppy love, love and happiness, love on the rebound.

Write in a paragraph what you consider to be the component parts of love and suggest changes that may occur in home relationships with increasing age.

Vocabulary:

abortion
affectional feelings
animosity
belligerent
cervix
clitoris
code
coitus
conception
courtesy
egg cell or ovum
embryo
fallopian tubes
fertilization
fetus
heterosexual
hymen
illegitimate parents
infatuation
menstruation
ovaries
ovulation
peer group
penis
pituitary gland
placenta
popularity
pregnancy
puppy love
ramification
romance

Basic Understandings	Suggested Experiences & Activities
scrotum semen sperm cells testes umbilical cord uterus vagina venereal disease vulva	

Culmination and Evaluation

Have students review the basic understandings that have been developed in this unit.

Have them discuss what they learned from these understandings, what effect they have had on their thinking and behavior.

Give the students a test.

Have the students list the generalizations or principles that they recognize as considerations which they can use in their future plans.

UNIT IV - Looking Toward Marriage

Suggested Time - 4 weeks

Overview

In our present day society where social mores and values are undergoing severe changes from the puritanical way of life to an exagerated emphasis upon freedom, family life education must establish some guide lines which will enable young people to choose wisely their life-time companion. This unit, therefore, should emphasize the basic concepts and understandings with which young adults need to be equipped when their thoughts turn to the serious consideration of marriage partners.

Specific Objectives

Goals in this unit are designed to help young adults to:

- Learn why people marry
- Gain an understanding of marriage responsibilities
- Recognize readiness for marriage
- Acquire knowledge of basic factors to be considered in choosing a marriage partner
- Recognize the value of the engagement period
- Learn of available community services for engaged couples
- Know how to plan and arrange an appropriate wedding.

Basic Understandings	Suggested Experiences & Activities
People marry for different reasons. It is important to understand motivating reasons.	List and discuss the many reasons that motivate people into marrying. Compare these with the reasons that were operative in the early days of our country. Determine which of the above reasons have a fair chance of resulting in a successful marriage. Why? Discuss why some of these reasons are almost certain to result in marriage failure.

Basic Understandings	Suggested Experiences & Activities
	Use case study references from library. Have one or two students bring in case reports. Reference: - Bernard, J., Buchanan, H. E. & Smith, W. E. - Dating, Mating and Marriage Film: - It Takes All Kinds Discuss the advantages and disadvantages of being married. Determine from vital statistics the number of persons who marry today. Compare with earlier times. Why the difference?
Understanding the meaning of present day concepts relating to marriage gives a background for wiser decisions on the part of young people. These concepts include: - Romantic complexes - Romance and love - Companionship - Happiness and well-being - Partnership - Promotion of personality growth.	List answers which students give to the question, "Of what do you think when you see the words: - marriage - romance - love - partnership - happiness and well-being - companionship - helping the other person to grow - improving one's marriage partner?" Discuss and evaluate. Have students examine ideas on romantic love presented by magazines, TV, etc. Discuss the degree to which these ideas represent a sound or misleading philosophy regarding marriage. Have students discuss, "When is love the kind of love upon which a real marriage may be built?" Discuss ideas or qualities that make for a lasting marriage.

Basic Understandings

Before becoming engaged, young people need to have an understanding of the responsibilities of marriage

- legal
- spiritual (sacredness)
- economic
- social
- procreative.

Suggested Experiences & Activities

Invite married individuals of long standing and of lesser standing to discuss the responsibilities which are assumed when

- a girl marries
- a boy marries.

Invite an older married couple to discuss with the class some of the advantages of being married

- for the woman
- for the man.

Develop with the students a questionnaire which they could use to obtain information relating to responsibilities that a boy and a girl assume when they marry. Have the students interview couples of different ages and different experiences.

Read the marriage vows, discussing the implications of each statement.

Discuss the meaning of "vow". Relate the word vow to contract or contractual agreement.

List and discuss the responsibility assumed in marriage by the man and the woman. Discuss the essential contributions which each should make to marriage.

Evaluate the phrase frequently heard, "I am not marrying the whole family".

Consider the implications of the phrase, "marrying into a family".

Reference:

- Duvall, E. M. & Hill, R. - When You Marry, High School Ed., p. 149-150

Film:

- Early Marriage

Basic Understandings	Suggested Experiences & Activities
Being ready for marriage has many facets.	Outline and discuss the many facets of being ready for marriage. Formulate a list of maturity characteristics that make for marriage readiness. Reference: - Force, E. S. - Your Family Today and Tomorrow, p. 143-155 Discuss the implications of the phrase "emotionally and socially ready for marriage". Film: - When Are We Ready for Marriage Have students do library research on the divorce rate for early marriages as well as those contracted at a later age. Discuss. Refer to appropriate articles in current popular magazines. Start the students on a class card file summarizing current articles. Use 5" x 8" cards. Have the student list at the top of each card name of article, source, name of student, and summary of the main ideas of the article. Refer to this file for class use. Study and discuss, "How Do I Know When I Am Old Enough for Marriage?" as outlined in Landis, J. T. & M. G., Personal Adjustment Marriage and Family Living, p. 147-157 Discuss: - Marriage in high school - Marriage and military service. Have a R.O.T.C. officer or other service man give the point-of-view of the military toward marriage while serving.

Basic Understandings	Suggested Experiences & Activities
	Discuss: - Financial readiness for marriage - Elopement and secret marriages. Film: - This Charming Couple Discuss.
There are some background factors which tend to influence success in marriage. Knowledge of these factors may be guide lines for young people.	Have students discover the results of research studies which have been made on background factors that influence success in marriage. References: - Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 123-157 - Force, E. S. - Your Family Today and Tomorrow, p. 157-169 - Duvall, E. M. & Hill, R. - When You Marry, High School Ed., p. 113-131 In choosing one's lifetime companion discuss the relative importance of the following factors: - Age differences - Length of acquaintanceship - Attitudes, interests, standards, goals - Outstanding personality characteristics - Family and cultural backgrounds - Physical and mental health - Religious beliefs - Parents' attitudes and approval. Have each student outline and discuss: - The kind of marriage partner he would like to be - The kind of marriage partner he would like to find. See Appendix B.

Basic Understandings	Suggested Experiences & Activities
	Films: - Choosing for Happiness - Choosing Your Marriage Partner Have each person consider his own strengths and weaknesses in terms of characteristics outlined above. Have the students read about the importance of religion in choosing a life-time companion. Reference: - Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 177-188 Have a minister, priest and rabbi discuss with the class the importance of religion to marriage and family life. Discuss the concerns that parents have in the marriage of their sons or daughters.
The engagement period serves many useful purposes.	Have students list the purposes and values of the engagement period as they see them. Follow with reading and further discussion. Reference: - Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 159-170 A student panel could discuss the degree of agreement there should be on important purposes and goals of living before marriage. Reference: - Duvall, E. M. & Hill, R. - When You Marry, High School Ed., p. 87-110

Basic Understandings	Suggested Experiences & Activities
	Discuss the implications of widely varying attitudes on the part of husband and wife toward patterns of living involving money, in-laws, children, religion, recreation, work, etc. Have students develop some ways of reconciling these differences. Have students read and report on engagement and marriage customs of other cultures. Discuss the values recognized in these customs which differ from marriage customs in the United States. Discuss the meaning of: - Polygamy - Polygyny - Polyandry - Monogamy. Film: - Meaning of Engagement
The state government is related to the marriage of every person.	Have students obtain and discuss the most important laws pertaining to marriage in several states and the State of Missouri in particular. Reference: - Landis, J. T. & M. G. - Building A Successful Marriage, p. 259-279 Discuss state legal requirements for obtaining a marriage license. Have a lawyer explain changes in legal status of the man and the woman when marriage takes place. Study the brochure With This Ring, Missouri Bar Association.

Basic Understandings	Suggested Experiences & Activities
The engaged couple needs to be aware of community services available.	Have students list the services available to an engaged couple in an urban community. Discuss the advantages of using these services. Invite resource persons to discuss: - Premarital counseling - Premarital medical examination. Film: - Are You Ready For Marriage
Adequate knowledge about wedding plans and costs may help the young couple in planning more realistically the type of ceremony, reception and honeymoon which will be most appropriate for them.	Discuss the different types of weddings that may be planned. List the advantages of each type. Introduce the bride's book with directions for conducting a wedding. Outline in detail the necessary steps in arranging a simple or a more elaborate wedding. Consider: - Engagement announcements - Setting the date - Conference with the minister or the person who will administer the vows - Factors which will determine the type of wedding - Shower parties - Bachelor party - Responsibilities of the bride and groom and their families - Place to live - Furnishings. Evaluate the cost of a simple and an elaborate wedding in terms of permanent values. Outline plans for several different types of honeymoon. Discuss advantages of each type.

Basic Understandings	Suggested Experiences & Activities
	References: - Duvall, E. M. & Hill, R. - When You Marry, High School Ed., p. 134-165 - Anderson, W. J. - Design For Family Living, p. 99-104
There are times when it is wiser to break an engagement.	Discuss circumstances which might make it expedient to terminate an engagement. Consider how this might be done with the least damage to both parties. Reference: - Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 166-171
There are many reasons why some people do not marry.	References: - Force, E. S. - Your Family Today and Tomorrow, p. 128-134 - Landis, J. T. & M. G. - Building A Successful Marriage, p. 91-99 Invite a resource person to discuss reasons why some people do not marry. Consider: - responsibilities - careers - health - opportunities - disturbing experiences - parent-attachment. Outline ways a person, even though not married, may live a purposeful life. Reference: - Ogg, E. - Why Some Women Stay Single, Public Affairs Pamphlet

Basic Understandings	Suggested Experiences & Activities

Vocabulary:

affinity
community services
companionship
consanguinity
counseling
cultural background
elopement
engagement
honeymoon
legal status
marriageable
marry
monogamy
officiate
polyandry
polygamy
polygyny
premarital
procreative
readiness
romance
romantic complex
vital statistics
vows
wedding

Culmination and Evaluation

Administer an objective test covering the concepts and understandings which should have been gained from this study.

Use five-minute discussions on such topics as "My marriage readiness, plus or minus"; "When I am of age, I can choose a life-time partner", "I plan to be a bachelor, and so"; "Marry in haste, repent at your leisure"; "Johnnie married Susie, but he didn't intend to".

Have students write a paper on personal insights they have developed during the study of this unit.

UNIT V - Marriage - A New Way Of Life

Suggested Time - 3 weeks

Overview

In a world of profound and accelerating change, the two people who unite together in marriage have much to learn about each other and what it means to be married. Building a lasting marriage is a life-long task; a good marriage doesn't accidentally happen! As the marriage relationship changes and grows, the will to succeed is of primary importance in the marriage way of life.

Specific Objectives

The goal of this unit is to develop an understanding of:

- The meaning of marriage
- The concept that building a successful marriage requires planning, time, effort and cooperation
- The fact that adjustments must be made to successfully resolve conflicts
- The principles involved in determining the pattern of living for the new family unit.

Basic Understandings

The image of a successful marriage will help determine, at least to a degree, the kind of marriage which is apt to be developed.

Suggested Experiences and Activities

Have a panel of students discuss their ideas of a successful marriage of the "good life" each would like for his marriage.

Film:

- Marriage Today

References:

- Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 215-230
- Force, E. S. - Your Family Today and Tomorrow, p. 236-264

Basic Understandings	Suggested Experiences & Activities

	List and discuss:
	
	- Characteristics that each student expects in a husband or wife
	- Role of the wife in a new family
	- Role of the husband in a new family
	- Factors that may contribute to a satisfactory marriage
	
	  - planning and working together
	  - common goals
	  - playing together
	  - flexibility.
	
	References:
	
	- Landis, J. T. & M. G. - Building A Successful Marriage, p. 281-305
	- Anderson, W. J. - Design For Family Living, p. 107-114
	
	What can a wife do to keep the respect and affection she has won?
	
	What can a husband do to keep the respect and affection he has won?
	
	What is housekeeping? Homemaking?

The new family must learn to think, act, feel and plan as a couple. They must build the "we" philosophy of life.	Have students interview parents, teachers, ministers, business or professional people of various ages to acquire information about living as couples. Reference: - Duvall, E. M. & Hill, R. - When You Marry, High School Ed., p. 245-260 Have students develop a Family Responsibility Inventory. Discuss. See appendix B
The new family must share common interests, develop common goals and build new traditions.	Consider the value of traditions. List and discuss traditions which may be established during the early years of marriage.

Basic Understandings	Suggested Experiences & Activities
	Films: - Marriage Is a Partnership - This Charming Couple (if not used previously)
Adequate personality growth requires the development of individual interests and goals, on the part of both the husband and the wife.	Discuss the relationships of individual interests and goals to personality development and sound mental health. Consider how individual interests and shared interests can be harmonious. Discuss ways that married people can help themselves and one another fulfill their basic personality needs.
Since marriage is the most intimate and demanding of all human relationships, adjustment and conflict are inescapable parts of its nature.	Analyze the terms "conflict", "adjustment". References: - Duvall, E. M. & Hill, R. - When You Marry, High School Ed., p. 199-217 - Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 215-240 List and discuss some methods of resolving conflicts. Which are satisfactory, which unsatisfactory? Why? Six reasons for conflict are: - Process of living, growth and change - Fatigue and illness - Differences in values, goals and standards - Personality differences - Immaturity, jealousy - Unrealistic objectives. Discuss these reasons. Divide class into six groups. Have each group prepare a skit, using one of the six reasons for conflicts. Discuss possible solutions.

Basic Understandings	Suggested Experiences & Activities
	Bring clippings or articles to class showing differences in goals affecting married harmony. Discuss. Film: - Who's Boss
Every couple needs to learn and develop techniques for handling conflict situations	Discuss constructive and destructive ways of handling conflict or differences of opinion. References: - Bernard, J., Buchanan, H. E. & Smith, W.M. - Dating, Mating and Marriage, p. 258-294 - Force, E. S. - Your Family Today and Tomorrow, p. 204-219 - Landis, J. T. & M. G. - Building A Successful Marriage, p. 281-305 Developing an understanding of different methods of managing conflicts. Three of these methods are: - Domination by one person - Compromise-bargaining - Democratic planning. Through role playing, show different methods of managing conflict over one or more specific problems. Discuss such statements as: - "There are times when we should admit that we are wrong" - "I didn't have all the facts and need to reconsider" - "I'm sorry, I made a mistake". Films: - Jealousy - Handling Marital Conflicts

Basic Understandings	Suggested Experiences & Activities
Ability to communicate is basic in solving conflicts and releasing tensions in the new family.	Discuss the meaning of communication. List ways of communicating one with another. Which of these are helpful in developing understanding of each other. Review the importance of empathy in communication. Reference: - Anderson, W. J. - Design For Family Living, p. 138-140
Day by day, month by month the marriage relationship should continue to develop, grow and improve.	Discuss Duvall's concept of developmental stages in relationship to marriage. Emphasize year by year growth. Reference: - Duvall, E. M. - Family Development, p. 123-156 Have students interview adults who have been successfully married 5, 10, 30, 40 years to gain some information about husband and wife relationship changes and growth: - In companionship - In romantic ideas - In activities together and apart - In feelings of affection.
When a family cannot develop satisfactory ways of solving conflict there are sources of help in the community.	Invite guest speakers to discuss some of the resources in Kansas City available to the family. List sources of help and develop an understanding of the functions of: - marriage counseling agencies - family agencies - ministers - doctors - competent family members.

Basic Understandings	Suggested Experiences & Activities
	Discuss the importance of distinguishing between a bona-fide resource and quackery. Reference: - Where To Turn For Health and Welfare Services, Greater Kansas City Area, 1963

Vocabulary:

adjustment
bona-fide
catastrophe
code
compromise
controversial
depreciation
disillusioned
eugenic
harmonious
martydom
panacea
patterns
philosophy
prestige
quackery
reconcile
rigid
socio-economic
statistical
status
techniques
tension

Culmination and Evaluation

Have the students formulate the basic understandings which have been developed in this unit. Determine whether or not the following understandings have been included:

- Marriage is a way of living
- Marriages go through developmental stages
- Each marriage partner has a contribution to make to the personality development of his mate and to the development of a shared life

- If the marriage relationship is a dynamic one, differences of opinion and some conflict are bound to occur making adjustments necessary
- There are constructive as well as damaging ways of making adjustments.

Have each student describe in written form the personal growth he thinks would be necessary for him to make if he were to be married within the next year.

Have the class list problems which might be common to most marriages today. Use this as an introduction to Unit VI, entitled, Special Problems of Today's Family.

UNIT VI - Problem Solving For Today's Family

Suggested Time - 2 weeks

Overview

In today's family, there is emphasis on development of a group life which is satisfying in itself and at the same time contributes to each individual's growth. Growth on both an individual and a group basis in our fast moving society necessarily poses many problem solving situations. Finding solutions sometimes is difficult, often calling for consideration of new patterns of action in resolving conflict.

Specific Objectives

The function of this unit is to examine some of the problems which families face and some possible solutions.

The goal of this unit is to learn to:

- Recognize and identify problem situations in family relations
- Explore differential facts and opinions which are operative
- Examine and develop procedures for the logical consideration of facts and affective opinion looking toward formulation of possible solutions
- Select an appropriate solution and try it out
- Evaluate findings and decisions as they affect the family unit
- Seek a new solution when the previous solution has proved unsatisfactory.

Basic Understandings	Suggested Experiences & Activities
Husbands and wives, mothers and fathers need to consider periodically the areas in which there are apt to be differences of opinion.	List problem areas where differences of opinion are apt to occur, such as: - Social and recreational activities, individual, group - Work of the husband - Work of the wife, at home, away from home - In-laws · Sex behavior Children

Basic Understandings	Suggested Experiences & Activities
	- Religion - Emotional Needs and responses - Living quarters and conditions - Use of TV, radio - Freedom and responsibility of family members - Money management. References: - Mace, D. R. - Success In Marriage, p. 47-76, 111-129 - Anderson, W. J. - Design For Family Living, p. 107-148
The development of patterns of living in areas where there is apt to be differences of opinion is necessary.	Outline and discuss some of the possible patterns of living that might be developed in the previously mentioned areas. List advantages and disadvantages of these possible patterns. Invite resource persons to assist with the discussion. Discuss such ideas as: - "Marriage changes the social rules for each of the marriage partners" - "When or why should wives be employed outside the home" - "The wife contributes to her husband's success in his work" - "Take time to be a family" - "Men and women both should be interested in their community" - "Each member of the family sometimes should be alone."
There are many problems to which the family must give special attention.	Have the students read current library materials and discuss such problems as: - Suburban living - Mobility of the family - Human relations - The impact of mass media on family life - Housing - Automation.

Basic Understandings	Suggested Experiences & Activities
	Outline the factors involved in each of these problems. How do these apply to: - The newly established family - The family with preschool children - the family with elementary school children - the family with high school youth - the contracting family. Discuss implications of such ideas as: - "On the average, the modern family uproots itself every five years" - "Youth of today will probably have to train themselves to be competent in four or five different vocations before they reach retirement age" - "Mass media is an important factor in developing our ideals, standards of behavior and values" - "Suburban living turns mother into a chauffeur."
Decision making is a significant factor in family living today.	Have the students consider how decisions are made, who makes them, why they are important to today's family. References: - Duvall, E. M. - Family Living, p. 339-352, 369-396 - Sussman, M. - Sourcebook in Marriage and Family Living, p. 144-156 Emphasize with the students the role of each parent in decision making. Strive to develop the following concepts: - Parents are in the family for a real purpose - Growth is gradual from dependency to independency - The individual never becomes completely independent of his family unit - Respect for individual family members in decision making is a significant part of today's living.

Basic Understandings	Suggested Experiences & Activities
There are crises in every family. The family must find ways to meet these crises without disintegration of the family unit.	List the crises which are apt to be a part of family life such as: - Hospitalization - Loss of a family member - Separation - Disgrace, delinquency, crime - Infidelity - Non-support - Relatives moving in - Desertion - Loss of job - Mental illness - Venereal disease - Alcoholism - Illegitimacy References: - Duvall, E. M. & Hill, R. - When You Marry, High School Ed., p. 219-242 - Bernard, J., Buchanan, H. E. & Smith, W. R. - Dating Mating and Marriage, p. 353-391 Films: - Is There a Typical Family - Your Family Discuss: - The effect of these crises on family life - Family attitudes towards these problems - How can these experiences be used positively or to strengthen the family unit - What are the best ways to avoid total disintegration (think, plan, experience and maintain individual integrity).
Management of time and energy is an important aspect of today's living.	Have a homemaker, a business man or a professional person discuss management of time and energy.

Basic Understandings	Suggested Experiences & Activities
	Students may interview homemaker, business or professional person, if more convenient, and bring reports to class. Discuss. Have students do some scheduling of time and energy. Discuss implications of time and energy schedules to each family member. Discuss, "When time and energy are saved, what will be done with the concerned time and energy." Reference: - Smart, M. S. & R. C. - Living in Families, p. 311-328

Vocabulary:

contracting family
delinquency
democratic
desertion
disgrace
disintegrating
expanding family
family crisis
hospitalization
human relations
illegitimacy
infidelity
living quarters
management - time
energy
money
mass media
mobility of the family
pattern of living
privacy
schedule
sex behavior
social rules
suburban living
validity

Culmination and Evaluation

Have the students formulate the basic principles underlying this unit.

Discuss the importance of recognizing the rapidity of change which is occurring in our world and the impact which it is making on family life.

A panel may discuss how these changes may make for interesting and stimulating family living for each individual and for the group as a whole.

UNIT VII - Family Finance

Suggested time - 3 weeks

Overview

Developing a constructive philosophy about family finances and learning to adequately manage money are important factors in family life and in building a satisfactory marriage. In a very few generations the family has changed from being primarily a production unit to a consuming unit. This basic change leads to the importance of understanding money management.

Specific Objectives

The goals of this unit will emphasize:

- Understanding that there are basic principles involved in sound financial management of the family income
- Recognizing that family needs, values and desires determine the use of the family income
- Budgeting or planning use of income
- Learning how to evaluate consumer services and goals
- Developing resistance to sales pressure and false advertising.

Note - It is suggested that in this unit attention be given to specific materials relating to finance in order that the students will gain definite information about budgeting, credit, insurance and principles of consumer buying.

Basic Understandings

Good management of finances helps a family to live better on the income they have.

Suggested Experiences & Activities

Have students discuss meaning of:

- management
- plan or budget
- finances
- income.

References:

- Duvall, E. M. - When You Marry, High School Ed., p. 175-197
- Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 253-266

Basic Understandings	Suggested Experiences & Activities
	Have students write the ideas immediately suggested when the term "money" is mentioned. Follow with discussion of values and goals as relating to money.
Understanding personal finance is preliminary to managing family finance.	Have students develop and keep an accounting record for personal expenditures - relate to their actual income. Have them develop a personal budget for a specific period of time.
In any expenditure of money a fundamental question is, "Can we afford it?" Probably the first "afford" question is "Can we afford to get married?"	Divide the class into couples as far as possible. Have each group calculate cost of establishing a place for living (apartment, house, furnished or unfurnished). Consider the standard of living in their community, different age groups and salary levels. Reference: - Anderson, W. J. - Design For Family Living, p. 118-122 Discuss: - Amount of income which is desirable before marriage - The income which is necessary to establish minimum living quarters - Immediate financial responsibilities - The cost of future needs, wants and aspirations.
Adequate use of money requires planning - budgeting. Planning requires knowledge of the expenditures which most frequently occur. Planning also requires setting of goals and determination of values - immediate and long range.	Films: - Home Management - Why Budget Have the students discuss: - Why budget - What is a budget - How to use a family budget - Importance of relating expenditures to income.

Basic Understandings	Suggested Experiences & Activities
Categories which need to be considered are: - Shelter - Food - Clothing - Utilities - Transportation - Taxes - Insurance - Personal expenses - Recreation & education - Savings - short time goals, long time goals - Contributions - Gifts - Advancement or personal growth	Have committees set up operating family budgets for simple establishments for a definite period of time. Use catalogs, newspaper prices, store prices, etc. Consider and discuss the various items and ways of providing for both immediate and long range values and goals. Discuss how democratic principles of living may be applied to money matters in today's family as it changes, grows and matures. Films: - Home Management: Buying Food - Dollar Series filmstrips, Institute of Life Insurance. References: - A Date With Your Future, Institute of Life Insurance (free) - Craig, H. T. - Thresholds for Adult Living, p. 346-368 - Money Management Series - Household Finance - A Guide to Budgeting For the Young Couple - U. S. Dept. of Agriculture, Home and Garden Bulletin, No. 98.
Income is an important part of family finances.	Have class read appropriate references from books, magazines, newspapers. Reference: - Duvall, E. M. - When You Marry, High School Ed., p. 187-189 Discuss such topics as: - Sources of income - Whose income - Reasons for married women being employed outside the home - Who handles income - Who makes decisions about expenditures?

Basic Understandings	Suggested Experiences & Activities
	Reference: - Peterson, E., "Working Women" - Daedalus, Spring, 1964, p. 671-699
Every family needs to establish a credit rating.	Use student reports, committees or resource persons to consider and discuss: - Meaning of credit rating - Its value - How established - Kinds of credit - Institutions which loan money - Installment buying - Charge accounts - Banking arrangements - Loan sharks - The pitfalls of "Too easy credit". Films: - The Wise Use of Credit - How Banks Serve - Using Bank Credit References: - Phillips, E. B. & Lane, S. - Personal Finance, p. 53-84 - Using Our Credit Intelligently, National Foundation for Consumer Credit - Phelps, C. W. - Using Installment Credit - Force, E. S. - Your Family Today and Tomorrow, p. 314-315
The family needs to understand that taxes are necessary to help pay for the many services we enjoy.	Have the students make a list of the tax-supported services the family enjoys. Discuss taxes with the students - Federal - State and local - Social Security

Basic Understandings	Suggested Experiences & Activities
	Calculate the taxes which a family pays. References: - Teaching Taxes, U. S. Government, Dept. of Internal Revenue - Your Social Security - secure from Social Security office - If You Become Disabled - secure from Social Security office. Use resource persons from local Social Security office.
In today's world an insurance program is beneficial to the family.	Discuss factors which determine the kind of insurance - Life insurance, objectives, types of policies, premiums - Health insurance, objectives, types, how purchased - Car insurance, coverage - Property insurance, personal property, mortgage insurance, types of policies, coverage - Family plans for comprehensive coverage. Invite a resource person to discuss different kinds of insurance. Consider, "Can a family be over-insured? under insured?" References: - Craig, H. T. - Thresholds to Adult Living, p. 386-398 - Family Guide to Property and Liability Insurance - Insurance Information Institute - Phillips, E. B. & Lane, S. - Personal Finance, p. 374-420

Basic Understandings	Suggested Experiences & Activities
	Film Strips - Institute of Life Insurance: - How Life Insurance Began - How Life Insurance Operates - How Life Insurance Policies Work - Planning Family Life Insurance.
Before buying the family should consider the type of house, how it will be financed, and what the upkeep will cost.	Study and discuss factors involved in deciding whether or not the family should buy a house. If the decision is "yes", study factors involved in selecting the type to buy, where to secure loan, cost of the loan, etc. Use resource persons (Mr. J. D. Farmer, Home Savings Association). Film: - How to Buy a House (from Home Savings Association) References: - Craig, H. T. - Thresholds to Adult Living, p. 369-384 - U. S. Savings & Loan League - Safeguards of Freedom (secure from Home Savings Association).
There are ways to increase the family's real income even when the money income is not increased.	Have the students interview a number of homemakers to determine the ways by which their real income is increased. Have the students make a study and discuss the values in carefully planned buying and avoidance of high-priced luxury items. Develop some principles of consumer buying which enable money to be well spent. Discuss the meaning of impulse buying. Have the students make a study of the many ways in which waste may occur. Discuss unnecessary spending as waste.

Basic Understandings	Suggested Experiences & Activities
	Discuss the effect of high pressure salesmanship through mass media on family and personal buying and waste. Compare cost of expenditures for items such as bakery goods, simple sewing, etc., when produced at home from basic materials and purchased ready-to-use from the store. Do the same for simple house repairs done by the family or done by outside service persons. Discuss the creative values involved when family members produce at home. Resource persons: - University of Missouri, Extension Service, Mrs. Lois Harrison (on good buys) - U. S. Pure Food and Drugs, Mrs. Lorena Meyers (on quackery).
As the family becomes established financially, thought should be given to a savings and investment program.	Consider with the class the following types of savings and investments for different types of families: - Buying a home - Government bonds - Other types of bonds - Mutual funds - Stocks, preferred, common - Savings accounts. Discuss the need to develop a plan for investments which will provide income for the contracting family. . . when retirement from active earning occurs. Consider: - Social Security - Annuities - Stocks, bonds. Accumulation of property through investment makes it important to provide for its disposal at the time of death. Discuss the legal involvement and the necessity for wills. Invite a lawyer as a resource person.

Basic Understandings	Suggested Experiences & Activities
	References: - Craig, H. T. - Thresholds to Adult Living, p. 398-410 - Crabtree, A. P. - You and The Law, p. 165-176, 125-138
In today's world there are a number of places in which the family may keep their money.	List the places where the family may keep its money, such as: - At home - Banks - Savings and loan companies - Credit unions. Discuss the advantages and disadvantages of each.
As the family grows and matures, financial plans need to be revised.	Have the students revise their plans made at the beginning of the unit, including ideas learned during the past few weeks. Have them outline a family budget which would include the cost of the first baby from the beginning of pregnancy until the baby is six months old.
When a family has money problems, psychological problems are apt to develop.	Discuss the tensions, irritations and other psychological problems that are apt to be related to money problems of the family. What does "keeping up with the Joneses" mean? When is it wise or unwise to do installment buying? Reference: - Hoeflin, R. - Essentials of Family Living, p. 244

Vocabulary:

abstract
annuity policy
automobile insurance
- bodily injury liability
- collision
- comprehensive physical damage

Basic Understandings	Suggested Experiences & Activities
- medical payments - property damage liability - protection against uninsured motorists	
bonds budget charge accounts check commission common stocks confidence games consumer economics consumer price index convertible co-signer credit credit unions deed default depreciation dividends equity endorsement endowment policy fraud group insurance health and accident insurance home-owners liability coverage	
- comprehensive personal liability - medical payments - physical damage to property of others	
home-owners policy hospitalization insurance income installment buying interest limited payment life policy medical insurance mortality rate mortgage mutual funds preferred stock premium promissory note	

Basic Understandings

repossess
revolving charge account
savings and loan
straight life insurance
term insurance

Culmination and Evaluation

Have the students outline briefly the different times in the family cycle when revision of the family financial plan is likely to be necessary, indicating the changes that would need to be made and the reasons why.

Have a panel discussion on "Ways in which our concepts of family finance have been changed by this unit".

UNIT VIII - Children Are Added To The Family

Suggested Time - 6 weeks

Overview

Parenthood, a challenge, responsibility and a privilege, comes to the majority of young married couples within the first few years of marriage. Rearing children with reasonable success should bring real satisfaction and personality growth to both parents.

Specific Objectives

This unit aims to develop an understanding and appreciation of:

- Parenthood, its satisfactions and responsibilities
- Adjustments which must be made as children are added to the family
- Growth, behavior and principles for guidance of children
- Adjustments when there are no children.

Basic Understandings	Suggested Experiences & Activities
To introduce the unit the teacher may wish to post appropriate pictures, cartoons, a birth certificate and/or baby pictures of students (without names) on the bulletin board.	
The miracle of birth - a new baby grows for nine months before it is born into the world.	A young couple with their first baby may be invited to visit the class. Have the mother and father discuss the meaning of this experience to them. Assist the students in acquiring pertinent facts about the miracle of prenatal growth and the growth process. This may be achieved by showing films, reading and discussion.

Basic Understandings	Suggested Experiences and Activities
	Films: - Biography of the Unborn - Human Reproduction - Human Growth - Before Baby's Birth Day References: - Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 301-308 - Duvall, E. M. - When You Marry, High School Ed., p. 272-284 - Duvall, E. M. & Hill, R. - Being Married (teacher's use) p. 353-372 - Anderson, W. J. - Design For Family Living, p. 171-179 - Duvall, E. M. - Love and The Facts of Life, p. 123-137 - U. S. Dept. of Health, Education & Welfare - Prenatal Care - Lerrigo, M. O. & Senn, M. - Parents' Privilege. Discuss with the students "We Are Pregnant".
Each baby comes into the world with an inheritance, a product of both father and mother.	Discuss with the class hereditary factors and their application. References: - Anderson, W. J. - Design For Family Living, p. 151-170 - Duvall, E. M. & Hill, R. - When You Marry, High School Ed. p. 263-272 - Duvall, E. M. - Love and The Facts OF of Life, p. 137-143. Films: - Human Heredity Discuss, "From whom does the baby inherit his characteristics?"

Basic Understandings	Suggested Experiences & Activities
The prenatal period gives time for prospective parents to develop new understandings and make certain adjustments.	Invite a new mother and father to discuss necessary understandings and adjustments that have to be accomplished during the prenatal period. Have students interview new parents whom they know and bring to class new ideas concerning understandings and adjustments that need to be made by prospective parents. Have students consider the expenses that will be incurred and discuss necessary adjustments in the budget.
Medical care during the prenatal period is important to the health of the mother and the baby.	Have a nurse discuss with the class the importance of early selection of a doctor and the health care of the mother. Reference: - Anderson, W. J. - Design For Family Living, p. 176-177, 185
When the baby and mother come home new learnings must take place. An important area will be that of physical care and feeding of the baby.	Have a nurse discuss with the class the physical care of the infant. Have her demonstrate with a large doll how to bathe, hold and feed a baby. Films: - Caring For the Baby - Baby Meets His Parents - Protecting Baby From Infection References: - U. S. Dept. of Health, Education & Welfare - Prenatal Care, p. 63 - Shuey, R. M., Woods, E. L. & Young, E. M. - Learning About Children, p. 125-141 - Graves, J. - Right From The Start, Public Affairs Pamphlet Discuss the relationship between the baby's physical care and feeding and the development of feelings of security

Basic Understandings	Suggested Experiences & Activities
New parents need to give thought to their roles as parents in building effective male and female parental images within the evolving family.	Have the students discuss such ideas relating to parenthood as: - Establishing lasting images - The role of parenthood - New adjustments with a new baby recognizing dependency and developmental stages of growth - The essential qualities of a good home - New relationships when there are three instead of two - How parents can maintain husband-wife identity in the midst of parenthood. References: - Anderson, W. J. - Design For Family Living, p. 189-191 - Duvall, E. M. - Family Development p. 192-195, 196-201 - Force, E. S. - Your Family Today and Tomorrow, p. 265-285, 236-254 Develop a series of generalizations which indicate the kind of parents we should like to become.
Grandparents may be an asset to the child.	Discuss the contributions which grandparents may make to the child. References: - Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 364-365 - Force, E. S. - Your Family Today and Tomorrow, p. 297-299
Children grow and develop according to a pattern. If the parent is to fulfill his role as a guidance counselor he must have some knowledge of the developmental cycle and the orderly process of growth.	Have the student discuss the meaning of developmental cycle, developmental pattern, growth and guidance. Outline and discuss the main developmental tasks to be accomplished at each developmental stage.

Basic Understandings	Suggested Experiences & Activities
	References: - Duvall, E. M. - Family Development, p. 35-43 - Duvall, E. M. & Hill, R. - When You Marry, High School Ed., p. 302-303 - Duvall, E. M. - Family Living, p. 307-312 - Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 309-322 - Shuey, R. M., Woods, E. L. & Young, E. M.-Learning About Children, p. 142-164 Consider how parents provide for the growth needs of the child - emotionally, physically, spiritually, intellectually, socially. Reference: - Hoffman, M. L. & L. W. - Child Development Research, Vol. I Film: - Preface To A Life Study and discuss the following: - All behavior is caused - Dependence gives way to independence - Building self-confidence and self-image - Developing a feeling of trust - Promoting friendliness - Developing responsibility and problem solving ability - Establishing values and goals - Building respect for order and law - Encouraging initiative, curiosity, creativeness, sincerity and integrity - The whole personality must grow - The parental love for the child. Have a panel of young parents discuss privileges and responsibilities of parents in guidance of children.

Basic Understandings	Suggested Experiences & Activities

Have several young children brought to the classroom for visiting and observation.

Have students observe children of different ages in different situations in the community comparing behavior patterns and maturity levels.

Films·

- Ages and Stages Series
- Early Social Behavior
- Posture and Locomotion

References:

- Duvall, E. M. & Hill, R. - When You Marry, High School Ed., p. 24
- Duvall, E. M. - Family Development, p. 228-287
- Craig, H. T. - Thresholds To Adult Living, p. 253-274
- Shuey, R. M., Woods, E. L. & Young, E. M. - Learning About Children, p. 31-52.

Have students develop a chart using the following column headings:

Age of Child	Developmental Characteristics	Behavior Problems	Controls & New Learning
2 yrs			
3 yrs			
5 yrs			

Reference:

- Spock, B. - Baby and Child Care, p. 346-396

Organize a panel discussion on:

- "It's the mother's job to rear the children and the father's job to earn the money"

Basic Understandings	Suggested Experiences & Activities
	- "Every child should be treated equally" - "Discipline is making children behave". List some common problems in child rearing which parents usually face. Have committees discuss possible solutions. References: - Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 323-332 - Shuey, R. M., Woods, E. L. & Young, E. M.-Learning About Children, p. 181-186 - Stoops, E. - Here's How - Craig, H. T. - Thresholds to Adult Living - Duvall, E. M. & Hill, R. - When You Marry, High School Ed., p. 299-302 - Loeb, R. H. - Manners For Minors - Anderson, W. J. - Design For Family Living, p. 227-247
	Consider the kind of sex education that the parents should provide for preschoolers, elementary children, high school youth. References: - Anderson, W. J. - Design For Family Living, p. 197-226 - Shuey, R. M., Woods, E. L. & Young, E. M. - Learning About Children, p. 275 - Christopher Records - Spock, B. - Baby and Child Care, p. 372-380
Parents will be more adequate in their jobs if they learn about child growth, behavior and relationships.	Review the need for learning about growth and behavior.

Basic Understandings	Suggested Experiences & Activities
	List the available resources in the community and discuss how they may be used. Acquaint the students with the parent education program promoted by the Department of Family Life Education, Kansas City, Mo. Public Schools.
New relationships and new problems develop when other children are added to the family.	Discuss ways and means of helping each child to adjust as the family circle expands. Film: - Sibling Rivalries and Parents Reference: - Puner, H. W. - Helping Brothers and Sisters Get Along, SRA booklet Have students discuss jealousy, rivalry, and other emotional problems which develop when there is more than one child in the family. Have students who are the oldest, youngest and middle children report on problems which they faced because of their special place in the family. Formulate possible aids to adjustment. Have students who are only children discuss some of their problems of adjustment. References: - Spock, B. - Dr. Spock Talks With Mothers, p. 59-94 - Puner, H. W. - Helping Brothers And Sisters Get Along, p. 15-23, SRA booklet
In today's society many mothers find it necessary to be employed outside the home.	Discuss with the students the reasons why mothers may be employed outside the home.

Basic Understandings	Suggested Experiences & Activities
	References: - Duvall, E. M. - Family Living, p. 257-258, 273-275, 341, 344, 355 - Shuey, R. M. , Woods, E. L. & Young, E. M - Learning About Children, p. 54-55 - Daedalus - The Woman In America, p. 671-709 Consider with the class the arrangements that may be made for adequate care of the children. Have the students discuss, "Adequate Care". Discuss with the class the adjustments that may need to be made by family members when the mother is employed. Have the students list the extra expenses that may be incurred when the mother is employed outside the home. Does the salary earned compensate for these extra expenses? Discuss the need for women to be full-time mothers when children are young.
As boys and girls grow older new child-parent relationships evolve which call for new family patterns of living and communications. Here, parents seek to guide the child as he or she approaches adjustments for more adult behavior and responsibilities.	Discuss the importance of maintaining friendly and cooperative communication in the family through the teen-age and young adult period of growth. Have students indicate and discuss areas of concern which call for thoughtful understanding on the part of both parents and teen-agers. Discuss the importance of: - mutual respect for the individual - compromising - personal honesty - respect for opinion and rights of others - sharing. Relate this discussion not only to their relationship with their parents, but, also, to their responsibilities later as parents.

Basic Understandings	Suggested Experiences & Activities
	References: - Neisser, E. - How To Live With Children, p. 41 - Osborne, E. - Democracy Begins In The Home, Pub. Affairs Pamphlet, p. 13 - Anderson, W. J. - Design For Family Living, p. 250-257 - U. S. Government - The Adolescent In Your Family, p. 57
As the children become young adults, the family becomes a launching center.	Have the students read and discuss the meaning of "launching center". Discuss relationships between parents and their adult children. References: - Anderson, W. J. - Design For Family Living, p. 283-287 - Craig, H. T. - Thresholds To Adult Living, p. 245 - Duvall, E. M. - Family Development, p. 335-388 - Duvall, E. M. & Hill, R. - When You Marry, High School Ed., p. 309
Childless couples who wish children may satisfy their need in different ways.	Discuss with the class the question of whether or not the home can be satisfying without children. If so, under what conditions? Consider the various ways of satisfying one's need for children when a couple is childless, for example: - Foster care - Adoption - Interest in other people's children - Church and Sunday School work - Community activities. Discuss relative merits of each.

Basic Understandings	Suggested Experiences & Activities
	Invite a guest speaker from a social agency to discuss foster care and adoption and the responsibility which one assumes in either plan. Have this speaker outline procedure for becoming a foster parent, an adoptive parent. Reference: - Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 347-352
Special kinds of adjustment are necessary when the home is broken by death, separation, desertion, divorce.	Brainstorm the class on the kinds of family adjustments that may or must be made when there is: - sudden death - separation - family desertion - divorce. References: - Landis, J. T. & M. G. - Personal Adjustment Marriage and Family Living, p. 285-300 - Sussman, M. B. - Sourcebook in Marriage and the Family, p. 440-483 - Duvall, E. M. - Family Living, p. 233-237, 341-342 - Force, E. S. - Your Family Today and Tomorrow, p. 346-358 - Craig, H. T. - Thresholds to Adult Living, p. 200-203, 234 - Duvall, E. M. & Hill, R. - When You Marry, High School Ed., p. 219-241 - Hoeflin, R. - Essentials of Family Living, p. 247-250 - Anderson, W. J. - Design For Family Living, p. 143 (reference on brainstorming)

Vocabulary:

adoption
birth certificate
discipline
family circle

Basic Understandings	Suggested Experiences & Activities
flexibility	
forceps	
foster parents	
fraternal twins	
identical twins	
incubator	
infant	
inflexible	
jealousy	
labor	
multiple birth	
obstetrician	
parental role	
parenthood	
pediatrician	
prenatal	
preschool child	
prospective parents	

Culmination and Evaluation

Review the book Angel Unaware by Dale Evans Rogers. Compare adjustments made to the normal child with those which must be made to the handicapped child.

Administer an objective test on facts presented.

If not done earlier in the unit, have each student write an essay on the kind of parent he would like to be and what steps he could take now and in the future to help him become this kind of parent.

Have students write a review of their own progress and development during the unit.

UNIT IX - The Older Generation In the Family

Suggested Time - 2 weeks

Overview

The "empty nest" era in a couple's life often presents completely new problems and opportunities. The ability to recognize each situation for what it is and to live accordingly may be the key to maintaining good mental health.

Numerous families are finding the approach of the retirement age either interesting or frightening. The relatively new concept of retirement from the working force in the early sixties leaves many couples in a dilemma not easily resolved. In addition, many families have older parents for whom they must plan. The increased life expectancy should urge us to consider, investigate and evaluate the role these people play in both the family and community life.

Specific Objectives

The goals of this unit are to learn to:

- Recognize the importance of planning for retirement and post retirement years of the life cycle
- Appreciate emotional aspects and attitudes relating to the empty nest
- Develop satisfying and creative use for new found leisure time
- Accept the physical changes which occur as we grow older
- Understand adjustments needed when husband or wife is left alone
- Acquire techniques and develop creative ideas for continuing social and civic responsibilities in the community.

Basic Understandings	Suggested Experiences & Activities
Since people are marrying at younger ages, many mothers and fathers find that they reach the "empty nest" stage at an age when they are still vigorous and alert. This stage brings new challenges, new relationships, new problems - a new way of living.	Review the family life cycle identifying the "empty nest" stage. Discuss the implications of this stage and the developmental tasks to be accomplished.

Basic Understandings	Suggested Experiences & Activities
	Discuss how women may spend their time and energy which was once used in rearing children. Evaluate these different ways in terms of promoting individual personality growth and in providing further integration of mother and father as a couple. References: - Duvall, E. M. - Family Development, p. 389-407 - Anderson, W. J. - Design For Family Living, p. 283-303 - Craig, H. T. - Thresholds To Adult Living, p. 245-246 - Duvall, E. M. - Family Living, p. 358-360 - Duvall, E. M. - When You Marry, High School Ed., p. 310-311 - Cavan, R. S. - The American Family, p. 482-496 - Whitman, H. - Your Middle Years
Parents frequently become grandparents, a status which calls for new adjustments and relationships.	Invite several grandparents to discuss with the class how they conceive the role of grandfathers, grandmothers. Discuss, "Grandparents are valuable people". Consider with the class the responsibilities and privileges of being a grandparent. Discuss how the younger family and especially grandchildren can make life better or worse for the grandparents. Use buzz sessions to help find suggestions for living with grandparents. References: - Landis, J. T. & M. G - Personal Adjustment Marriage and Family Living, p. 364-366

448

Basic Understandings	Suggested Experiences & Activities
	- Cavan, R. S. - The American Family, p. 504-505, 404-405 - Duvall, E. M. - Family Development, p. 407-430, 462-464 - Hoeflin, R. - Essentials of Family Living, p. 90, 153-154 - Duvall, E. M. - Family Living, p. 150-152, 279 - Stern, E. M. - A Full Life After 65, Public Affairs Pamphlet
Scientific and medical advances have made it possible for people to live longer.	Have the students develop individual charts, graphs or posters which help analyze statistical materials concerning older population groups on city, state and national levels. The same may be done for the numbers of various age groups in our total population. References: - Use the public library as a pivot of reference - include Statistical Abstracts of the United States, World Almanac, Population Perspectives and other current reference materials.
With advancing age, there are physical, emotional and spiritual changes.	Have resource persons discuss some of these changes and their meaning or have the students read in this area. Consider physical limitations, health, emotional and social problems. Have the students discuss the question, "What is meant by the aging process?" Have the students make a study of ways that some of the emotional needs of older people might be met. Reports might be made on Golden Age Clubs, Service Corps for Senior Citizens, etc.

Basic Understandings	Suggested Experiences & Activities
	References: - Hart, E. - Making The Most of Your Years, Public Affairs Pamphlet - Anderson, W. J. - Design For Family Living, p. 296-303 - Metropolitan Life Insurance Company, When Our Parents Grow Old - John Hancock Life Insurance Company, Growing Old Gracefully - Jacobs, H. L. - Youth Looks at Aging - Lawton, G. & Stewart, M. J. - When You Grow Older, Public Affairs Pamphlet - Cavan, R. S. - The American Family, p. 500-504
	Discuss with the students the pros and cons about relocation of residence for older persons - Within the community - In a warmer climate - In a village or apartment for older people.
	Have the students discuss the financial and other responsibilities that should be assumed by grown children for one or both parents when their income or Social Security may not be sufficient to meet the necessary expenses of old age.
	The teacher may need to point out the reciprocal responsibilities which grown children assume as they become the independent members of the family and their parents become the dependent ones.
When it becomes impossible for older people to maintain their own home or be cared for by their grown-up children, there are supplementary services available.	Have students discuss possible health insurance plans and their cost, cost of nursing home care and private home care. Discuss licensing for nursing homes in Missouri (Information may be secured from the Division of Health of Missouri)

Basic Understandings	Suggested Experiences & Activities
	Assign students to report on current articles dealing with care of older persons.
Widowhood is a state through which many must pass.	Discuss with the students preparation for widowhood including learning to live again on a single basis.
	Invite a minister, priest, or rabbi to discuss the function of the church in relation to older widows or widowers.

Vocabulary:

- empty nest
- golden age clubs
- launching center
- licensing
- medicare
- nursing home
- population groups
- retirement age
- senior citizens
- widowhood

Culmination and Evaluation

Have a panel discuss "Mental health and happiness in older age are determined by the kind of life one lives before he reaches the status of older age", and "Whether one is happy or sad depends upon whether one is at peace, not merely with the world, but with himself".

Have another panel discuss the responsibility of those in their teens, 20's, 30's, 40's and 50's for taking the loneliness out of old age.

UNIT X - The Individual and The Family Live in the Community

Suggested Time - 2 weeks

Overview

In our society, the family and community are interrelated and each is responsible, one to the other. The family depends upon the community for many supportive services. The community, on the other hand, is made up of individual families, each of which has responsibility to the whole. Young people today stand at the threshold of another cycle.

Specific Objectives

This unit will emphasize:

- The contribution which a community makes to its families
- The responsibilities each family has to contribute adequately to the neighborhood, city, state, nation and world.

Note: Some teachers prefer to cover this material in the previous units rather than to devote a separate unit to it. If this has been done adequately, there is no need for repetition. It is organized here, however, for the use of teachers presenting it as a separate unit and to serve as suggestions for content and activities when it is incorporated into other units.

Basic Understandings	Suggested Experiences & Activities
We cannot take advantage of the opportunities provided by the community, if we are unaware of community services.	Ask the students the question, "How much do you know about your neighborhood and Kansas City, Missouri?" Survey the neighborhood and city for the services provided for families and family members. Make notes on the values of each service - also approximate expense involved in utilizing these services. Investigate such services as: - Protective services - Public utilities - Cultural and recreational opportunities

Basic Understandings	Suggested Experiences & Activities
	- Health and welfare - Character building Have a resource person discuss services provided and how a person avails himself of these services. Have students write term papers or give reports concerning findings. Reference: - Where To Turn For Health and Welfare Services - Greater Kansas City Area, 1963
Every city has forces and conditions which are not helpful to the development of healthy personalities or wholesome family life.	Have students discuss some of the detrimental influences which they recognize in their community. Discuss how individuals and/or families may counteract such influences. Have a panel discuss services and community influences on the basis of "Youth wants to know".
The individual and the family, if each is to benefit from the community, must also contribute positively to the community.	Have the students present reports on: - "How we as individuals can contribute to healthy community development" - "The responsibility of each family to its neighbor and to the community". Have a panel discussion on the kind of family our neighbor would like to have living next door. (Students may interview several families for data.) Discuss family responsibility for supporting: - the church - the laws - youth programs - governmental and political activities - education - cultural activities - welfare programs - taxes, etc.

Basic Understandings	Suggested Experiences & Activities
	Develop an understanding of the full meaning of the term "support" (time, energy, money). References: - Duvall, E. M. - Family Living, p. 39 - Cavan, R. S. - The American Family, p. 511-533 - Force, E. S. - Your Family Today and Tomorrow, p. 361-390 - Craig, H. T. - Thresholds to Adult Living, p. 290-304
Youth needs to have an understanding of the inner city plight and the influence of economic deprivation on individual and family development.	Have students investigate this basic understanding in relation to Kansas City. Use resource persons to help clarify the picture. Evaluate the progress being made in our city. Resource persons: - Mr. Jim Reefer, Director of City Welfare, Kansas City, Missouri - Mr. Robert MacNeven, Special Consultant, Commission on Human Relations, 16th Floor, City Hall, Kansas City, Missouri. Film: - Children Without
Vocabulary: character building services community counteract cultural deprivation health services influences inner city protective services support supportive services welfare services	

Culmination and Evaluation

Invite a well-informed person to give a summary discussion on the responsibility of the family to the community and vice versa.

Have students write a report on practical steps which they themselves can take to better their neighborhood.

UNIT XI - The Family, 1965-1975 Style

Suggested Time - 1 week

Overview

This unit should serve as a summary for the Family Relations Course. It gives an opportunity to review, to clarify, to enlarge upon and to emphasize some of the most important basic principles and learnings that have been established throughout the school year.

This course has sought to help the student:

- See himself as an individual, understand the growth or developmental process as it applies to him, and accept for himself the goal of furthering his own fulfillment. Students need to have developed the concept that each individual is unique. This uniqueness must be developed in a way satisfying to the individual and to society

- Understand the great importance of the family in the United States of America, its functions, developmental cycle, the principles of democratic living as applied to the group as a whole, and the values in uniqueness in patterns of family living

- Realize the importance to our national life of fulfillment for each individual, and how the family may contribute to the furtherance of learning and personality growth at every age

- Grasp the idea of the rapidity of change in the modern world and the inherent creative possibilities in change. If the concept of constant change can be accepted, the individual may act more effectively in determining his own life pattern, and in becoming a positive force in the community and in the nation.

Suggested Activities and Evaluation

Have the students project goals for family life looking toward the year 2000. *Use "Population Perspectives" as a point of reference. Imagine yourself in 2000. Will your homes be different - families - schools - churches? What part do you plan to play in progress?

Have the students write a paper on one of the following:

- The most meaningful experiences of the year and why (one method would be for the student to write to an imaginary friend in another location telling this friend why a high school senior should take this course)
- How their ideas, values, and goals have changed
- Why it is important to know one's values. In the paper they might outline their value system.
- Student chosen topic related to a unit studied this year (with teacher approval).

Ask the students to suggest course changes or topics which would have been beneficial to them.

* Hauser, Phillip - Population Perspectives, Rutgers University Press, New Jersey, 1961, $3.50

APPENDICES

APPENDIX A STYLE SHEET FOR WRITTEN WORK

I. FORM FOR WRITTEN WORK

A. Use blue or black ink or double-spaced typing for the finished copy of a composition.

B. Capitalize all words in a title except conjunctions (and, but, or, nor, etc.), prepositions of four letters or fewer (for, in, on, of, to, etc.), and articles (a, an, the.) Capitalize these also, if they are first or last in the title.

C. Write the title on the first line. Put no period after it. Put no quotation marks around it.

D. Leave space of one line below the title.

E. Indent about one inch for the beginning of each paragraph.

F. Start the first paragraph on the third line.

G. Leave one-inch margins on both sides of your paper and one and one-half inches at top and bottom.

H. Use only one side of the paper for the finished copy of a written composition. Use unruled paper, regulation theme-size.

I. Endorse the outside paper in the following form:

Jack Taylor
Subject
Hour
September 9, 1962

J. Fold lengthwise. (Optional)

II. CAPITALIZATION

A. CAPITALIZE

1. The first word of every sentence, direct quotation, topic of an outline, and line of poetry. (Modern poetry is not included.)
2. Languages, but not other subjects unless accompanied by a designation. (I take algebra and world history. I take Algebra 2 and World History I.)
3. Names of the month, days of the week, holidays, but not seasons.
4. All words in the salutation of a letter except Dear when used with my - - My dear Sir: Capitalize only the first word in the complimentary close of a letter.
5. Only names of particular buildings, business houses, churches, clubs, colleges, highways, lakes, mountains, oceans, organizations, parks, rivers, schools, seas, societies, streets. (Northwest High School.)
6. Names of cities, constellations, continents, countries, departments of government, historical events, nationalities, persons, places, states, steamships. (Indian; Battle of Bunker Hill.)
7. All words in a literary title except conjunctions (and, or, but, nor, etc.), prepositions of four letters or fewer, (for, in, on, of, to, etc.), and articles (a, an, the.) Capitalize these also, if they are first or last in the title.
8. The word Bible, the books of the Bible, and all words referring to God and the Deity. (But not the word god, if it means a pagan deity.)
9. Terms of relationship like Mother, Father, Grandmother when used without a modifier or before a person's name. (I saw Mother and Uncle John.) (See II., B., 3.)

10. North, South, East, and West when they are used as names of sections of the country, but not when they are used as names of directions. (The North defeated the South. Turn north now.)
11. Titles of office only when they precede a person's name - - Mayor Bartle. One exception is the President of the United States.
12. Commercial trade names - - Eversharp pencil, Boeing plane, Crosley radio.

B. DO NOT CAPITALIZE
1. Names of animals, birds, flowers, games, insects, and trees.
2. Class names like freshman, sophomore, junior, senior.
3. Mother, father when preceded by modifier, like my mother, her father.

III. PUNCTUATION

A. USE A PERIOD
1. At the end of every declarative and imperative sentence.
2. After initials of names.
3. After accepted abbreviations.
4. After numbers and letters used in numbering exercises or the topics of an outline.

B. DO NOT USE A PERIOD
1. After the title of a composition.
2. After the topics of an outline unless it is a sentence outline.
3. After your name when you sign a letter or note.

C. USE A QUESTION MARK - After every direct question.

D. USE AN EXCLAMATION POINT - To indicate strong or sudden feeling.

E. USE COMMAS
1. To set off all items, after the first, of a date.
2. To set off all items, after the first, in an address.
3. After Oh, Yes, No, Well, when they introduce a sentence.
4. To set off a noun of direct address.
5. To separate words, phrases, and clauses in series.
6. To separate parallel adjectives.
7. To set off words in apposition unless they are closely related to words they explain - - Ellen, my sister, - - my sister Ellen.
8. Before expressions like can't you, didn't she, doesn't he, don't they, hasn't he, haven't you, isn't she, won't you when they come at the end of a sentence.
9. To set off parenthetical words and phrases like as usual, by the way, however, nevertheless, no doubt, on the other hand, of course, etc.
10. To set off most direct quotations from the rest of the sentence.
11. After the salutation (greeting) of a friendly letter and after the complimentary close of all letters.
12. Before the conjunctions and, but, for, nor, or when they join unpunctuated independent clauses.
13. After an introductory adverbial clause. Seventeen commonly used subordinate conjunctions that introduce adverbial clauses are: after, although, as soon as, because, before, if, since, though, unless, until, when, whenever, where, wherever, while, why, as.
14. To set off nonrestrictive clauses - - Mr. Smith, who is sick, is our friend.
15. To set off all introductory participial phrases, or phrases containing participles that turn or delay the thought - - A flock of ducks, flying very high, passed over our blind.

F. USE AN APOSTROPHE

1. To form the possessive case of nouns and indefinite pronouns.
2. To indicate the omission of a letter or of a syllable in a contraction.
3. To form the plural of figures, letters, signs, and of words when the latter are spoken of as words: 1's, L's.

G. USE QUOTATION MARKS

1. To enclose the words of a speaker in a direct quotation.
2. To indicate the titles of articles, chapters, short stories, and single poems when quoted from a publication.
3. To indicate titles of movies, radio, and television programs.
4. To indicate foreign phrases not italicized.

H. USE AN UNDERLINE

1. Under each separate word of titles of books, magazines, and newspapers, long poems, plays, musical works, planes, ships, and trains.
2. Under letters, figures, and words used in sentences as letters, figures, and words - - Dot your i's and cross your t's. Can you spell Mississippi?

I. USE A SEMICOLON

1. To separate independent clauses not joined by coordinate conjunctions in a compound sentence - - Classes start at eight o'clock; a warning bell rings five minutes before the hour.
2. Between long independent clauses joined by co-ordinating conjunction when either clause is punctuated by commas - - Jones was chosen; but, I believe, Smith is the better man.
3. To separate terms of a series if commas are used within the terms - - The main characters are Tom Sawyer, a mischievous boy of eleven; Huck Finn, his pal; Sydney, his younger brother; Becky, his girl friend.

J. USE A COLON

1. After the salutation (greeting) of a business letter.
2. After such expressions as the following and as follows.
3. Before a long, formal quotation (but not if single spaced, and indented farther than the rest of your typewritten material.)

V. GOOD SENTENCE STRUCTURE - ESSENTIALS

A. PROPER RELATION OF IDEAS.

A simple sentence develops only a single idea. Complex or compound sentences contain a central thought and related ideas. Related ideas are expressed either in phrases or in subordinate clauses.

B. UNITY OF THOUGHT IN THE SENTENCE

1. Separate sentences should be used for ideas not closely related in thought.
2. Clauses in compound sentences should be of equal rank both in meaning and form. The complex sentence should be used when clauses are of unequal rank.
3. A series of short statements closely related in thought should be combined into one sentence.
4. A phrase or a dependent clause cannot be used as a complete sentence.

C. CLEARNESS OF THOUGHT IN THE SENTENCE

1. Place modifiers, such as adjectives, adverbs, phrases, and clauses, near the words they modify.
2. Make the reference of each participle and of each pronoun definite.
3. In general, keep the same number, the same tense, and the same voice throughout the sentence.
4. Use connectives that express exactly the desired relations between parts of complex and compound sentences.

D. EMPHASIS IN THE SENTENCE

1. Ideas placed at the beginning or at the end of a sentence receive emphasis.
2. Emphasis is secured by arranging words, phrases, or clauses in the order of increasing importance.
3. Emphasis is increased by omitting unnecessary words.
4. Emphasis is secured by using words that show exact distinctions.

V. PARAGRAPH STRUCTURE

A. A paragraph is a group of properly related sentences that develop a single topic. A topic sentence aids in the logical development of a paragraph. The following sentences are examples:

1. A city administration may be economical and not efficient.
2. A very common method of judging the efficiency of municipal government is to compare the cost of a given service in one city with the cost of the same service in another city.

B. A paragraph should concern itself with one and only one topic or main thought. Each sentence in the paragraph should contribute directly to the development of the paragraph topic. Close a paragraph with a sentence that summarizes, concludes, or emphasizes the topic, if added force is needed.

VI. THE OUTLINE

The following outline form will contribute to orderly thinking:

I. . . . . .
  A. . . . . .
    1. . . . . .
    2. . . . . .
      a. . . . . .
      b. . . . . .
  B. . . . . .
II. . . . . .

(The following points should be stressed in the making of outlines:

1. There cannot be a break into fewer than two parts. Consequently, in an outline, there cannot be a I. without a II., an A. without at least a B., a 1. without at least a 2., etc.
2. Entries under the parts of an outline must be parallel in importance as well as in form. For instance, if A. is "The uses of a slide rule" then B. cannot be something like "Advanced problems," even though the material is presented in that order in the book. B. might be something like "The advantages of a slide rule.")

APPENDIX B

Rating Charts, Inventories and Questionnaires

Item 1 - How Old Am I?

	Today	End of Semester	End of School Year
When someone disagrees with me			
When someone pokes fun at me			
When I want attention			
When I am confused			
When I don't get what I want			

Have rating computed in years. Example: 10 years old, 14 years old, etc.

Ask students to make three or more copies of chart and have the following persons rate them - a parent, a friend and themselves. Keep these for comparison at end of year.

Item 2 - Check List for Self-Understanding*

Check those items to which you could or would answer "Yes"

I. Accepting One's Physique

1. I think I am too big.
2. I think I am too tall.
3. I am smaller than most people in my class.
4. My clothes don't look as well as my classmates' clothing.
5. I don't like to fit patterns in class.
6. I think I'm well proportioned.

II. Learning New and More Mature Relations with Age Mates of Both Sexes

7. I enjoy dating.
8. I have many friends.
9. I like to go to parties.
10. I do not like to go to parties.
11. I enjoy mixed parties.

III. Acquiring Emotional Independence From Parents and Other Adults

12. I can make my own decisions.
13. My parents approve of my judgment.
14. My parents dictate to me.
15. I do not like to be corrected.
16. We often disagree at home.
17. My parents have confidence in me.

IV. Selecting and Preparing For an Occupation

18. I know what I am going to do for a living.
19. I want to do the same kind of work my father does.

* Courtesy of Home Economics Education Classes, University of Missouri.

20. I don't want to do the same kind of work my father does.

21. I want to work and earn a lot of money.

22. I want to be a doctor or a lawyer.

23. I wish I knew what I wanted to do for a living.

V. Acquiring Skills and Concepts Necessary For Civic Competence

24. I like to work with groups.

25. I would rather work alone.

26. I'm proud of my community.

27. My community needs to be improved.

28. I like to be a leader.

29. I would rather be a follower than a leader.

VI. Desiring and Achieving Social Responsibility of Behavior

30. I like to give parties.

31. I like to go to teas.

32. I like to plan teas.

33. I like to meet people.

34. Making introductions is fun.

35. I do not like to meet new people.

VII. Building Values in Keeping With an Adequate World Picture

36. We are all created equal.

37. I enjoy my grandparents.

38. To travel is fun.

39. Everyone has a right to his own religion.

40. We all have a right to our personal opinions.

41. Customs of other families and races are interesting.

VIII. Achieving Assurance of Economic Independence

42. I enjoy making my own money.

43. I believe a family should save.

44. I believe every family member of age should work.

45. My father doesn't earn enough money for us all.

46. Most of my friends have more than we can afford.

47. I'll be glad when I can earn my own money.

Item 3 - When Is A Person Grown Up?*

Read the sentence below. If you agree that what is said indicates being grown up, place a check beside the sentence under TRUE. If you think the sentence does not describe what it is to be grown up, check the FALSE column. If you are undecided, check the third column.

You are grown up when you:	TRUE	FALSE	UNDECIDED
1. start dating			
2. are twenty-one			
3. are willing and able to take responsibility for your acts			
4. are given a latchkey by your parents			
5. get a driver's license			
6. try to understand your parents and get along with them			
7. don't lose your temper if you do not get your own way			
8. live within your allowance			
9. vote for the first time			
10. begin to earn money			
11. see the other person's point of view			
12. don't cheat even if others do			
13. begin to "go steady"			
14. are willing to change your attitude after thoughtful deliberation			
15. learn to face up to problem, to solve it or learn to live with it			
16. can argue with your parents and win your point			

* Permission granted by Rev. Elton Smith, St. George's Episcopal Church.

Item 4 - Family Responsibility Inventory*

FAMILY RESPONSIBILITY INVENTORY

Encircle the symbol that represents the person or persons you expect will perform each task in your future family. Encircle H for husband, B for both husband and wife, and W for wife.

H	B	W	1. Doing the weekly grocery shopping.
H	B	W	2. Entertaining the children in late afternoon and early evening.
H	B	W	3. Managing the family's money matters.
H	B	W	4. Washing the car.
H	B	W	5. Bathing and dressing the children.
H	B	W	6. Being concerned with politics and world affairs.
H	B	W	7. Making repairs on household equipment.
H	B	W	8. Feeding the children.
H	B	W	9. Deciding where the family will live.
H	B	W	10. Doing the laundry.
H	B	W	11. Spending time with the boys in the family.
H	B	W	12. Preparing the meals.
H	B	W	13. Paying the bills.
H	B	W	14. Doing the vacuuming.
H	B	W	15. Choosing where we will go and what we will do when we go out for fun.
H	B	W	16. Planning the meals.
H	B	W	17. Staying home with the children during part of the weekend.
H	B	W	18. Doing the ironing.
H	B	W	19. Deciding on types of insurance policies for the family.
H	B	W	20. Doing the dusting.
H	B	W	21. Guiding the children's play activities.
H	B	W	22. Keeping clothes in repair.
H	B	W	23. Managing and planning for spending money.
H	B	W	24. Scrubbing and waxing floors.
H	B	W	25. Spending time with the girls in the family.
H	B	W	26. Drying dishes.
H	B	W	27. Decisions affecting the family as a whole, such as when meals are served and when television is turned on.
H	B	W	28. Washing dishes.
H	B	W	29. Babysitting in the evenings.
H	B	W	30. Selecting furniture for the house.
H	B	W	31. Setting social dates with other couples.
H	B	W	32. Washing windows.
H	B	W	33. Caring for the children when they are sick.
H	B	W	34. Serving meals or keeping the house orderly when we have guests.
H	B	W	35. Decisions concerning the children, such as where they will go and what they may do.
H	B	W	36. Rearranging the furniture.
H	B	W	37. Disciplining the children.
H	B	W	38. Buying gifts for holidays and birthdays for the children, relatives, and friends.
H	B	W	39. Deciding the place for the family vacation.
H	B	W	40. Cleaning up after guests have left.
H	B	W	41. Shopping for clothes for the children.
H	B	W	42. Emptying the garage.
H	B	W	43. Gardening or other lawn work.
H	B	W	44. Keeping informed and active in the work of the community.
H	B	W	45. Selecting small kitchen appliances.

* Permission to reproduce this Inventory granted by The National Council on Family Relations.

Item 5 - A Test On "Mate Selection"*

A student teacher at Texas Tech recently made many discoveries about her students when she used the following questions as a test over the unit of "Mate Selection":

How can happiness "run in families?" Is it inheritable" Explain and illustrate.

If one comes from an unhappy home, is he doomed to an unhappy future home? Is he doomed to an unhappy marriage? Explain.

What is the best guarantee that a couple will enjoy their leisure time activities together after they marry? Explain and illustrate.

"Marriage is no better than the material that goes into it." Explain.

What is your understanding of the term "mixed marriage"? Illustrate.

Many men protect their egos by dating and marrying those who are younger and who have the same or less education then they have. Discuss.

Determine the four most important characteristics which you could not tolerate in a marriage partner and give the reasons for your choice.

Do you consider this statement to be true?: "It is more important to be the right person than to find the right person." Why or why not?

* Tips and Topics in Home Economics - Vol. IV, No. 2, December 1963, p. 8 - Permission to reprint this material granted by the School of Home Economics, Texas Technological College, Lubbock, Texas.

Item 6 - Questionnaire on Marriageability

Questions which each partner should be able to answer in the affirmative before marriage.

1. Are we both mature enough so that personality needs will not greatly change in the next few years?

   Between the years of 17 and 24 most people change greatly. The person one loves at 17 might not suit at all five years later.

2. How many important interests do we have in common? Do we both genuinely enjoy the same kind of books, some of the same activities or sports? Or is one of us bored by many of the things that seem enjoyable to the other? Do we see humor in the same situations? Or is one of us serious and intense about something that seems funny to the other?

3. Are our backgrounds similar enough so that we could understand each other readily in marriage? (The importance of difference in religion, race, and other factors has been discussed in another chapter)

4. What about the family of the person I love? Are they a happy, congenial family? If he (she) comes from an unhappy family, has it marred his personality?

5. What do my family and friends think of him? If he embarrasses me around them, is it because I am overly sensitive, or is it that he (she) really does not fit in with the other people I care for?

6. Do we quarrel? A few quarrels may occur in almost all courtships, but many quarrels mean that there will be many quarrels in marriage. Many quarrels must be recognized as a sign that something is wrong, a danger signal warning that trouble is ahead if these two people marry each other.

7. Am I confortable around this person? That is, can I be my real self or do I feel that I must work hard to live up to some of the expectations he (she) has for me? Do I feel that I must try to appear to be different from what I am?

8. How well do we agree on roles of men and women? Does one of us believe in equality and the other believe in the male-superior and female-inferior pattern in life? That kind of a difference does not help love to grow later.

9. Have we been acquainted long enough to know how well we agree on important matters, or have we been so busy making love that we just assume that we agree on everything?

10. How much do we confide in each other? People who confide in each other are establishing a good pattern for their future happiness.

11. Would I want to change this person if I married him (her)? It probably cannot be done.

12. Do I respect his (her) judgment? Are there many occasions when it seems to me that he makes the wrong decisions or choices?

13. How mature are we both? Have we learned the differences between love and physical attraction? Can we look at marriage objectively, or are we basing our ideals and expectations upon romantic stories or movies?

14. Do we have the same goals in life? Are we going in the same direction, so that we can happily strive for the same things?

Item 7 - The Family Life Cycle*

* Permission to reproduce this chart granted by the American Social Health Association.

Item 8 - The Family Cycle*

* Hoeflin, R. M. - Essentials of Family Living, p. 91. Permission to reproduce this chart granted by John Wiley & Sons.

Item 9 - Every Third Worker Is a Woman*

* President's Commission on The Status of Women - American Women, Women's Bureau, Department of Labor, Washington, D. C., 1963, p. 28

Item 10 - Most Women Who Work Are Married*

* President's Commission on The Status of Women - American Women, Women's Bureau, Department of Labor, Washington, D. C., 1963, p. 29

Item 11 - Too Many Children Lack Good Care*

TOO MANY CHILDREN LACK GOOD DAY CARE

* President's Commission on The Status of Women - American Women, Women's Bureau, Department of Labor, Washington, D. C., 1963, p. 21

Item 12 - Births Out of Wedlock Are Increasing*

BIRTHS OUT OF WEDLOCK ARE INCREASING

Among the 202,000 babies born out of wedlock in 1957 there were about 81,000 whose mothers were teenagers, about 5.2 percent more than the number born out of wedlock to teenage mothers in 1956. But this does not mean that illegitimacy among teenage girls is increasing disproportionately. While the numbers of teenage marriages and teenage mothers increased, the proportion of teenage girls bearing children out of wedlock remained the same for 1956 and 1957. This is a significant fact since this is the first time since 1940 that there has been no increase in the rates of births out of wedlock to teenage girls.

About 40 percent of all mothers of illegitimate babies are under 20 years of age, about 2 percent are under 15 years. While the proportion under 15 years has not changed significantly since 1938, there is a trend toward smaller proportions for the 15 to 24 year old group and correspondingly larger proportions for those 25 years and older.

Item 13 - Letter Which Is Mailed Early in the School Year to Parents of Students Enrolled in Family Relations

SCHOOL DISTRICT OF KANSAS CITY, MISSOURI
DIVISION OF INSTRUCTION
DEPARTMENT OF FAMILY LIFE EDUCATION

October, 1965

Dear Parents:

Your boy or girl is enrolled in the family relations course in your high school. Since this is a relatively new area of instruction in our schools, we thought you would like to know a little more about it.

Almost every individual spends the major portion of his lifetime living in a family situation. It seems important, therefore, that we give our young people as much help as possible to live well in their parental families and to create happy homes of their own at a later date. It was with this thought in mind that the course entitled Family Relations was introduced into our high schools. In general, this course seeks to foster good mental health, sound values, and to strengthen and enrich family life. Enclosed is a brochure outlining the units of study which are included in this course.

A fee of $1.00 each semester is charged each student. Since students are not required to buy a textbook, this fee is used to purchase a variety of reading materials which are available to all enrollees in the class.

The family relations class meets daily for the entire school year. It is open to senior students.

Any time that you would like to know more about this class, you are invited to consult with your family relations teacher, your school principal, or you may call Dr. Esther E. Prevey, Director of Family Life Education, School District of Kansas City, Missouri - Ba 1-7565, extension 233.

We hope this class will prove beneficial and interesting to your son or daughter.

Sincerely,

Family Relations Teacher

INTRODUCTORY BUSINESS FOR EVERYDAY LIVING

This is a learning activity package to help you understand basic business terms and ideas as they apply to consumers and producers.

Rationale (Why Study This?)

The purpose of this Learning Activity Package is to expose you to business and economic affairs that will affect your everyday life and well-being. It will enable you to develop an understanding of our economic society. Our purpose will be accomplished through direct, clear, accurate, and lively presentations in which business principles and basic economic ideas are explained by relating them to experiences we have in living and working in America today.

This study will lead us to units concerning money, finance, insurance, law, and economic factors operating in our business world.

Primary Idea

The main idea you should obtain from this study is "What Business Can Do and Does For You." This information will come from the secondary ideas that follow.

Secondary Ideas

1. You Live in a Business World.
2. Business Satisfies Your Wants Through Production.
3. Business Markets Your Goods.

Instructional Objectives (or Goals)

To help you find the information the work is divided into smaller objectives (goals) and activities. Below is a list of these:

I. The student will domonstrate his understanding of the selected business terms by being able to:

   A. Define each term in his own words
   B. Relate each term to given business situations
   C. Apply the use of these terms to given business situations

II. Given knowledge of the basic business terms, the student will demonstrate the way in which the production of goods and services satisfies our needs and wants by ability to:

   A. Explain relationship of goods and services to production
   B. Give examples of the factors of production
   C. Explain the effect of production on the standard of living

III. The student will demonstrate his knowledge and understanding of the three steps in marketing goods by his ability to:

   A. Define each step in his own terms
   B. Give examples of each step
   C. Explain the relationship of marketing to production and consumption

HOW TO USE THIS LAP!

STOP, LOOK, AND LISTEN! ! ! Then follow these directions. This LAP is an introductory LAP. It is divided into three segments. Each segment is divided into three steps.

1. The Instructional Objective: What we expect of You. This tells you what skill or idea you will be expected to know or obtain from each segment.

2. The Activities: FUN, FUN, FUN !!!
   Required : These are activities all students must complete.

   Optional : These are activities any of the students may complete to learn more about the objective. (Extra Credit will be given for the GO-GETTER who completes one or more activity successfully.)

Exemption Procedures (How Do You Skip a Segment?)

After looking at and reading the content and objectives of this LAP, you may want to by-pass (Exempt) the unit. In this case:

1. Take the pretest. If you pass with 5 errors or fewer you may proceed with the exemption.

2. See the instructor for an exemption evaluation consisting of:

   A. An oral exam on content
   B. An evaluation of the content

3. If you are successful, proceed to the next LAP or complete parts of this LAP that interest you.

Required Activities

All nonexempted students will complete the required activities in their numerical order. Papers are to be handed in to the instructor as soon as they are completed and you go on to the next activity. The papers will be evaluated and returned. Some required activities are labeled a or b or c or d. This means that you may choose any one of them or all if you so desire.

Optional Activities

These activities are designed to provide greater understanding for those who wish to learn more about the unit. Extra Credit will be given on the unit grade. When you have finished your Optional Activities be sure to turn them in to the instructor for evaluation.

STUDENT EVALUATION CHART

Inst. Objective #	"Should Time"	Time Taken	Optional Activities Completed	Extra Credit	QUANTITY	QUALITY	TEACHER TEST	FINAL AVERAGE

							Final Average	

PRETEST

Everyone takes the pretest. Check your answers with answers on page 32 of this LAP. If you miss only 5, you can take the teacher test. If you miss more than 5 questions, you must start activities on page 10 of the LAP.

		True or	False
1.	Satisfying just one person's needs may require the efforts of many people.	T	F
2.	Farming is no longer the largest single industry in the U.S.	T	F
3.	Competition may exist even between different types of business.	T	F
4.	Over the years, man's wants and needs have decreased.	T	F
5.	One of the easiest decisions consumers have to make is how to spend money.	T	F
6.	All businesses in this country (a) are interdependent (b) require raw materials (c) require machinery (d) are successful.	_____	
7.	Competition forces businesses to (a) pay high wages (b) expand (c) advertise (d) be efficient	_____	
8.	Define: goods		
9.	Define: consumer		
10.	A bank is an example of a service type business.	T	F
11.	A free-enterprise system discourages competition.	T	F
12.	Consumers determine the kinds of things our business system porduces.	T	F
13.	A nation's standard of living depends on its population.	T	F

14. Fewer people earn a living by working for someone else than by operating businesses of their own. T F

15. Efficient production is as important to workers as it is to the owners of business. T F

16. The amount of goods and services a worker can obtain in exchange for one hour of labor has been steadily decreasing. T F

17. Production is the result of combining labor with natural resources and (a) technology (b) advertising (c) capital (d) specialization. _____

18. Define: producer

19. All businesses engage in manufacturing. T F

20. Today practically no one produces all the things that he needs. T F

21. The process of getting goods from producers to consumers is marketing. T F

22. One marketing function that is required for all production is (a) storage (b) packaging (c) processing (d) transportation _____

23. Converting raw materials into finished products is called (a) marketing (b) specialization (c) division of labor (d) manufacturing _____

24. Define: 3 functions of marketing

25. Define: marketing

Now grade your test. Answers on page 31 of LAP

INSTRUCTIONAL OBJECTIVE #1 TIME: 4 days

The student will demonstrate his understanding of the selected business terms by being able to:

A. Define each term in his own words.
B. Relate each term to given business situations.
C. Apply the use of these terms to given business situations.

TURN TO NEXT PAGE

Required Activities

Complete #1 and #2, then the balance in any order you desire. Remember * is in Quality Score, page 6 of LAP 1.

1. Write a two paragraph paper on what you expect to gain from this course.

2. Read on of the following (or both for additional information.)
   a. Pages 4-16 in GENERAL BUSINESS, 2nd Edition
   b. Pages 1-7 in GENERAL BUSINESS, 3rd Edition

Special Everyone view "A Better Way." (Time and place to be announced.)

*3. Complete Vocabulary and Understanding on page 13.

*4. Complete Projects and Problem #1 on page 14.

*5a Alone or with some other student write the answers to Sharing and Discussing Your Problems on page 15.

OR

5b Sign up for and attend a small group discussion to discuss Sharing and Discussing Your Problems, page 15 in LAP 1.

Optional Activities

Complete as many of these in any order as you wish.

1. Business information is often presented by means of tables, charts, or graphs in order to show comparisons or relationships. For example, the table below shows five of the largest companies in the U.S., measured by the number of employees.

Company	# Employees
Ford Motor Company	160,181
United States Steel	225,081
General Motors	595,000
Standard Oil Company of NJ	140,000
General Electric Co.	250,621

a. List the companies in order of their size as measured by employees. Begin with the largest.
b. Find the total number of people employed by these companies.
c. The average number employed by these companies was _____ (Number employed by all - number of companies = average # employed)

2. Read or reread pages 12-16 in GENERAL BUSINESS, 2nd Edition and complete Learning by Doing on pages 17-18, Parts 2 and 3 in text.

Vocabulary and Understanding

Vocabulary

Select from the column that term best suited for the statement and write it in the appropriate blank.

goods	producer	consumer
industry	services	luxuries
	producer goods	

1. Material objects, such as books or cameras. _____
2. Things others do for us, like cutting our hair or repairing our cars. _____
3. A group of business enterprises that produce similar products or provide similar services, _____
4. A person or enterprise that makes goods or provides service. _____
5. Goods used to produce other goods or services. _____
6. Goods and services that give pleasure but are not considered necessities. _____
7. Anyone who uses the goods and services of business. _____

Understanding

For each of the questions, indicate your answer by checking Yes or No.

	Yes	No
1. Do most persons today produce the goods they consume?		
2. Are there more farms in the United States than any other type of business?		
3. Is every employed person a producer?		
4. When we say that businesses are interdependent do we mean that they are not dependent on one another?		
5. Do most people depend on business for employment?		
6. Is the primary purpose of business to satisfy our needs and wants?		

		Yes	No
7.	Do most stores produce goods?		
8.	Could only one business satisfy all our wants?		
9.	Could our business system thrive without consumers?		
10.	Does the demand for business products and services increase as our population increases?		
11.	Does what consumers select in the way or products and services have little effect on our business system?		
12.	Is it easy for consumers to decide how to spend their money, since business produces so many goods and services?		

Projects and Problems #1

For each item listed below indicate by a check mark in the appropriate column whether it is a good or a service.

	Goods	Services		Goods	Services
Clothing			Insurance		
Electric Power			Air Transportation		
Gasoline			Telegraph Message		
Hotel Accomodations			Truck Repair		
Hair Cut			Desk Lamp		

List five businesses in your community that produce goods. For each company, list one item it produces. Indicate in the appropriate columns whether the items are made for consumers, producers or both.

Name of Business	Item Produced	For Consumer	For Producer
Example: Roger's Dairy	Milk and cream	X	X
1.			
2.			
3.			
4.			
5.			

Name five types of businesses--either manufacturing or service--on which each of the businesses listed below depends. For example, restaurant depends on such businesses as food supplier, furniture manufacturers, etc.

Filling Station	Barber Shop	Grocery Store	Lumber Yard
1.			
2.			
3.			
4.			
5.			

Sharing and Discussing Your Problems

1. Food is not the only product of our farms. Can you think of other ways in which our farms contribute to production?

2. Does consume mean the same thing as use? Explain.

3. Do you think people can learn to be good consumers?

4. Relate a personal experience in which satisfying one need gave rise to other needs, such as the example of buying a phonograph.

5. Carefully examine this textbook and name at least three different kinds of businesses that might have helped to produce it.

6. Give example of articles that may be either consumer goods or producer goods.

7. Bill Wright maintains that people were more independent in earlier times than they are today. Do you agree? What do you think he means?

8. Primitive man satisfied his wants in a direct manner. Today people satisy their wants in an indirect manner. Explain.

Self-Evaluation

See instructor to go over required activities and those optional activities completed by you, and record on STUDENT EVALUATION CHART.

Complete the following STUDENT SELF-TEST. If you complete 4 out of 5 accurately and to your satisfaction, go on to Instructional Objective #2. If you feel you need additional work on the objective, see the instructor.

Student Self-Test

Write at least one paragraph for each of the following.

1. Business is a means of satisfying our wants and needs. What does business do for you?

2. Why are consumers important in our business system?

3. Give examples of how one business depends on other businesses.

4. Explain the difference between goods and services.

5. What caused farming to become a business today?

INSTRUCTIONAL OBJECTIVE #2 TIME: 4 days

Given knowledge of the basic business terms, the student will demonstrate the way in which the production of goods and services satisfies our needs and wants by ability to:

A. Explain relationship of goods and services to production
B. Give examples of the factors of production
C. Explain the effect of production on the standard of living.

Required Activities

Special! Everyone view a film on "What is Business." This film will be shown during large group activity. (Time and place will be announced.)

1.a Read "Business Satisfies Your Wants Through Production" in GENERAL BUSINESS FOR EVERYDAY LIVING.
Pages 19 to 24 in the 2nd Edition
Pages 10 to 14 in the 3rd Edition

OR

1.b Listen to a tape recording of pages 10 to 14 from GENERAL BUSINESS FOR EVERYDAY LIVING, 3rd Edition. Follow along in your textbook as the information is being read.

*2. Complete the vocabulary and understanding activity pages 20 and 21 of this LAP. You are welcome to use the textbook. Do you remember what * means? Why not find out on page 5 of LAP 1.

*3.a Explain the statement that "All Businessmen Engage in Production" orally to your instructor.

OR

3.b Write a short paper (two or three paragraphs) explaining how a nation's standard of living is closely related to its gross national product.

4.a Sign up and attend a small group discussion on the topics listed on page 22 of LAP 1.

4.b Individually, or with another student, write a brief reply to each of the topics listed on page 22 of LAP 1.

Optional Activities

1. Select an article manufactured in your community and list the raw materials needed to produce it.

   Example: Raw materials needed to produce shirts
   1. cotton cloth

   Raw materials needed to produce_____

_____ _____

_____ _____

_____ _____

2. List six types of production being carried on in your community by young people about your age.

_____ _____

_____ _____

_____ _____

_____ _____

3. Make a list of capital goods that might be used by one of the following kinds of business enterprises: clothing store, shoe-repair shop, railroad, mining company.

   Example: Capital goods required for a clothing store
   1. display cases

   Captial goods required for a _____

_____ _____

_____ _____

_____ _____

4. List goods and services you believe a family must have in order to have a high standard of living.

GOODS AND SERVICES NEEDED FOR A HIGH STANDARD OF LIVING

_____ _____

_____ _____

_____ _____

_____ _____

Vocabulary and Understanding #2

Vocabulary

Read the statements below; then for each statement, select the term that best matches it in meaning. Write this term in the space provided.

capital	mass production
demand	natural resources
division of labor	producer
factors of production	production
gross national product	profit
income	specialization
labor	standard of living
	technology

1. Changing the form or location of natural things to satisfy human wants ___. _____

2. Every businessman expects to earn a fair ___ on his business. _____

3. Natural resources, labor, and capital. _____

4. Things in existence that man did not produce, such as timber, oil, and iron. _____

5. We manufacture hundreds of automobiles daily. This is called ___. _____

6. The human effort that goes into production. _____

7. When an article is produced by many workers who each do only one part of the job, it is __. _____

8. Man-made things used in production. _____

9. A way of dividing production, so that each worker performs only one job. _____

10. When a knowledge of science is applied to production, we call it ___. _____

11. Money received by business from the sale of goods and services. _____

12. The amount of a good or service that will be bought at a particular price. _____

13. Mr. Jones manufactures plastic toys; Mr. Abel sells them, each is a ___. _____

14. The total amount that a nation produces in a year. _____

15. The way a family or the people of a nation live. _____

Understanding

Understanding directions. Each of the following statements is either true or false. If the statement is true, circle the "T" at the right; if false, circle the "F".

1.	Doctors and lawyers cannot be called producers, since they perform only services.	T	F
2.	Production is a minor function of business.	T	F
3.	Production includes not only making goods but transporting and selling them as well.	T	F
4.	A free-enterprise system permits you to select your own occupation.	T	F
5.	Goods used up in production, like office supplies and fuel, are called working capital.	T	F
6.	The term capital goods refers to the money needed to obtain goods used in production.	T	F
7.	Although mass production provides more goods, it increases their cost.	T	F
8.	Some things are produced without capital.	T	F
9.	Production is the result of combining labor with natural resources and capital.	T	F
10.	Iron and coal are natural resources.	T	F
11.	Specialization is a division of labor.	T	F
12.	Income is the result of production.	T	F
13.	Gross National Product is always expressed in dollars.	T	F
14.	The more workers specialize, the more dependent they are on one another.	T	F
15.	A nation's standard of living depends on its population.	T	F

When you have completed this activity test, check with your instructor. He will check your answers so that you may know how well you did.

Sharing Your Opinion and Experience

1. Joan Wilson earns extra spending money by baby-sitiing after school and on week-ends. Is Joan engaged in production? Why?

2. Why is farm land considered a natural resource?

3. What experience have you had as a producer?

4. Explain the statement, "Today production is based on teamwork."

5. How would you describe your community? Is it known as an agricultural area, a trade center, or a manufacturing center?

6. Give two or three examples of how weather influences what people buy.

7. Give some examples of goods that are not mass-produced.

Self-Evaluation

When you have finished the required activities and those optional activities you wish to do, check your progress by answering the following questions. Understanding these guide-posts gives you command to move on to Instructional Objective #3. If you are not comfortable with these ideas, see your instructor for some help.

1. People who make goods or provide services for others are known as producers. Explain how providing services can be called production.

2. The factors of production are natural resources, labor, and capital. Explain or give an example of each factor.

3. What do we mean by "Standard of Living" and how do we measure it?

4. What is production? Why is it the principal function of business?

? ? ? Have you been keeping your Student Evaluation Chart up-to-date ? ? ?

INSTRUCTIONAL OBJECTIVE #3 TIME: 4 days

The student will demonstrate his knowledge and understanding of the three steps in marketing goods by his ability to:

A. Define each step in his own terms
B. Give examples of each step
C. Explain the relationship of marketing to production and consumption

Required Activities

SPECIAL! Everyone attend film "The Making of Life."
This film starts in the forest and ends in pages of Life magazine. (Time and place will be announced.)

1.a Read pages 17-21 in GENERAL BUSINESS FOR EVERYDAY LIVING, 3rd Edition

OR

1.b Read pages 27-32 in GENERAL BUSINESS FOR EVERYDAY LIVING, 2nd Edition

OR

1.c Listen to tape of Chapter 3, Third Edition.

When you have finished this page, turn to page 26 of this LAP.

More Required Activities

You have read or heard a lecture about business markets goods. Now you do two of the following on this page. As soon as you finish one, go on to the next one. Do not wait.

*2.a Write answers to all thirteen questions of the Vocabulary and Understanding on page 28 of LAP 1. Don't forget to hand paper to teacher when you get all thirteen questions answered.

OR

*2.b Orally discuss all ten questions on Checking Your Reading Questions on page 29 of LAP 1 with one classmate. When you finish, record this on your Student Evaluation Chart.

OR

*2.c Sign up for and attend a small group discussion to discuss the following questions. Be ready to contribute information and not noise. Teacher will grade you on class participation.

Give examples of simple forms of distribution.

What determines the cost of marketing different items?

Which do you think would cost more to distribute--goods or services?

What are some of the ways consumers add to the cost of distribution?

What does * mean? Read page 6 of LAP 1 again for answer. Turn to page 27 for optional activities.

Optional Activities

Choose and do two of the following.

*1. Find pictures in magazines or draw pictures of six products and make a poster. Under each picture write why they would not have been advertised 15 years ago. Put on bulletin board in Room ____.

2.a Sign up for small group discussion. We will discuss:

Explain why the process of marketing is sometimes called distribution.

Why do you think retailers and wholesalers are called middlemen?

What reasons can you give for the fact that the marketing costs for food have been rising at a faster rate than for most other products?

Self-service markets are one example of how businessmen have attempted to reduce marketing costs. Explain.

OR

2.b Write the answers for 2.a Have one classmate read your answers and write his opinion of how clear and accurate you answered each question. Have him sign his name at the bottom of your last page. Hand it to the teacher after classmate has signed it.

*3. Make a list of ten articles found in your home that you probably could not have if it were not for our system of distribution. After each one, explain why it would have been difficult for you to obtain it. Present this at a small group discussion as an oral report.

4. Record on tape Chapter 4, third edition of the textbook. (Instructions for using tape recorder will be explained by teacher.)

Now turn to page 29 of LAP 1.

Vocabulary and Understanding #3

Vocabulary

Do all thirteen questions on this page. Match sentences and words. Write answer in blank at right.

wholesaler	retailer	peddler
producer	middleman	functions of marketing
distribution		marketing

1. The process of getting goods from producers to consumers is ? . _____

2. A retailer is sometimes called a ? . _____

3. A business enterprise that sells directly to consumers is a ? . _____

4. A merchant who buys goods in large quantities and resells them in smaller lots is a ? . _____

5. Tasks that middlemen perform in the process of moving goods from the original producer to the point of final sale are ? . _____

6. ? is the process of getting goods from those who produce to those who buy. _____

Understanding

Answer the following with a check in the column.

	Yes	No
7. Is distribution an essential part of our business system?		
8. Is the process of distribution sometimes called marketing?		
9. Are manufacturers middlemen?		
10. In business, does a market involve both a buyer and seller?		
11. Would our standard of living be as high as it is without our system of distribution?		
12. Do most producers of goods sell them directly to consumers?		
13. Is the principal function of wholesalers to sell directly to consumers?		

Checking Your Reading

Read each question and discuss what you think is the best answer for each. If you do not agree, try to find correct answers.

1. Explain why marketing is a part of production.

2. What is the simplest form of marketing?

3. What determines how a particular product is marketed?

4. What determines the cost of marketing a particular item?

5. Name five functions of marketing.

6. Why do business enterprises advertise?

7. How is marketing related to our standard of living?

8. As a rule, what kind of products cost the most to market?

9. What is the simplest form of distribution?

10. How does a wholesale merchant differ from a retail merchant?

Self-Evaluation

Time to check your progress by answering the following questions. Write your answers. Do you need any help? If you do, see the teacher. If not, check the box below.

1. Unsually food products are more expensive to distribute than manufactured articles. Why?

2. Some goods are sold direct from producer to consumer. Name some goods and the reasons why they can be sold direct.

3. Is it necessary to have middle men today?

4. Explain this sentence. In some ways, our standard of living depends as much on the distribution of goods as it does on the production of them.

IF YOU . . .

scored low on first part of pretest, pages 8 & 9 of LAP 1, review Instructional Objective #1 on page 10 of LAP 1.

scored low on middle part of pretest, pages 8 & 9 of LAP 1, review Instructional Objective #2 on page 17 of LAP 1.

scored low on last part of pretest, pages 8 and 9 of LAP 1, review Instructional Objective #3, page 24 of LAP 1.

scored low on all of pretest, review all of LAP 1.

Now turn the page and find out what to do next.

Teacher Evaluation

You are now ready for the teacher test. Ask teacher for this. You need only a pencil or pen. Conference will be held when you hand in your test. Good luck.

89-80% correct for 4.9 - 3.0

100-90% correct for 6.0 - 5.0

79-70% correct for 2.9 - 1.0

69 or less recycle as directed by teacher

Did you have a conference (talk) with the teacher after you finished the teacher test? Do not go on until you do.

Pretest Answers

1. T
2. T
3. T
4. F
5. F
6. (a)
7. (d)
8. The products of business.
9. Everyone who uses the goods and services of business.
10. T
11. F
12. T
13. F
14. F
15. T
16. F
17. (c)
18. Persons who make goods or supply services.
19. F
20. T
21. T
22. (d)
23. (d)
24. Transportation, packaging, processing, storing, advertising.
25. The process of distribution.

The Plastics Education Foundation is a tax exempt corporation co-founded by The Society of the Plastics Industry and The Society of Plastics Engineers. The Plastics Education Foundation has as a primary purpose the promotion of plastics education programs. The activities of the Plastics Education Foundation are carried on by a variety of committees including the following: Industrial Arts Committee, Teacher Education Committee, Scholarships and Grants in Aid Committee, Vocational and Technical Education Committee, College Committee, Equipment Committee, Career Guidance Committee. A Board of Directors representative of both SPI and SPE governs Plastics Education Foundation activities and programs.

Foreword

The purpose of the "Plastics Education Guide" is to assist and encourage educational institutions on all levels and firms in the plastics industry in preparing and presenting planned programs of study in plastics. It is an attempt to bring together a wide variety of information and put it in one convenient reference guide.

The following pages will provide the reader with an indication of the various levels at which plastics can be taught, furnish a comprehensive list of reference sources, describe the trade associations that can be of specific assistance in presenting programs, list laboratory/testing and production equipment and finally supply a representative list of visual aids that can be used in presenting plastics courses. The manual was started in the summer of 1963 and is the first one of its kind. It is intended to be a guide rather than a compendium of detailed information.

We would like to take this opportunity of thanking the two editors of the guide, Mr. W.W. Rogers of the State University Agriculture and Technical College, Farmingdale, N.Y., who drew up the initial plan for the Guide and accumulated a great deal of material for eventual editing and arranging, and Mr. Anver S. Suleiman of International Plastics Industry Consultants, Inc., New York, N.Y., who carried out extensive editing and put the Guide into its final form. We are indebted also to Committee members for furnishing the material used. The Committee also thanks the Education Committee of the Society of Plastics Engineers for its great help and full cooperation in the preparation of this guide.

It is hoped that educators will find this publication of help in their various educational activities and that they in turn will aid us by their criticisms and suggestions. This information will assist us to keep the Guide up to date by the issuance of new editions.

Robert J. Ullery
Education Director
Plastics Education Foundation

Dr. Vivian T. Stannet, Chairman
SPI Committee on
Plastics Education - 1966

INTRODUCTION

Why Teach Plastics?

Education institutions at both the secondary and post-secondary levels should consider the advisability of developing plastics education programs. The need for trained plastics personnel occupationally has been established clearly as a result of a 1968 nationwide manpower study by the plastics industry. This study revealed a continuing need in the foreseeable future for large numbers of entry level employees at the semi-skilled, skilled, technician and engineering levels in the United States. The industry has professed its willingness to be helpful in the establishment of programs and also to pay substantially higher starting wages to persons employed subsequent to having had special plastics studies in their preparation.

The plastics industry has grown dramatically in the last several decades. Such growth has averaged 15% per year, four times that of the Gross National Product. In 1983, it is estimated that the volume of plastics used for all purposes will exceed the volume of metals. Already production of plastics materials exceeds that of non-ferrous metals. Continued growth of plastics as an engineering material, both independently and as a part of the growing appliance industry, building construction, in electronics, in packaging, and in automotive applications assures ready employment for trained persons in the future.

The Plastics Education Foundation has as a primary purpose the development of improved educational opportunities for persons interested in a career in plastics.

Educators wishing to consider the development of plastics training programs are encouraged to take advantage of services of the Foundation early in planning stages. The Foundation can be particularly helpful in the identification of advisory committees and in many other ways on a regional basis.

Please let the Plastics Education Foundation assist in the development of your educational program for the future in an exciting area, Plastics!

Robert J. Ullery
Education Director
Plastics Education Foundation

I. Educational Levels and Course Outlines

Starting in elementary school, continuing through high school and college, and into industry, education is imperative in every field of endeavor. Plastics is no exception. The needs at these different levels vary as do the types of materials and methods of presentation. In the following section there will be an attempt to classify these various levels and provide an indication of the goals and type of training required. Of course, there will be some overlapping based on the practices of educational institutions, industry, and state requirements, but the principles can be applied readily by the thinking educator.

A. LEVELS AND OBJECTIVES

1. Secondary education...

a. **Industrial arts**, as a school subject, is the broad study of the materials, organization, tools, processes, products, jobs and the human problems of industry. It is developed through the planning and construction of projects of interest to students, and by discussions, observations and readings related to industry. It is taught through grade 12.

b. **Vocational training** is designed primarily for those students who may not go on to college and it prepares the individuals for specific roles in industry. Vocational training is education for advantageous employment in a specific occupation and is generally presented in grades 9 through 14.

c. **Technical training** provides extensive knowledge of a field of specialization and is usually offered in a post-high school institution. The curriculum consists of mathematics, sciences, and engineering processes as related to the specific field.

2. College and University...

a. **Associate degrees** (two years) are designed to develop the skills, basic knowledge, proper attitude, and appreciation for successful entrance and advancement in the field as a technician.

b. **Bachelor's degrees** (four years) can be obtained in the engineering, science or technology areas.

c. **Graduate degrees**, either master's or doctoral, are extensions in specialization of the type of training received at the undergraduate level. It includes the successful completion of an independent piece of research in the chosen field.

3. **Company training programs...**

   Every raw material supplier, most of the equipment suppliers, and many of the molders and users of plastics have developed internal training programs devoted either wholly or partly to plastics. These programs which vary in degree of formality and specialization are geared to a wide range of employee levels.

4. **Industry training programs...**

   This category includes short courses, seminars, conferences, etc. offered by universities, professional corporations, and trade associations.

5. **Correspondence courses...**

   This type of training is starting to develop in the plastics industry.

B. REPRESENTATIVE COURSE OUTLINES

1. Secondary Education

a. Industrial Arts - The increase in plastics courses in industrial arts education during the last decade has been significant. Concurrent with the offering of such courses has been the development of course outlines and other curriculum materials. One of the first such outlines was developed in the State of New York by the Bureau of Industrial Arts Education. This outline has been reprinted by the Plastics Education Foundation. The publication is entitled, An Experimental Resource Unit in Plastics for Industrial Arts.

Data concerning curriculum materials available from State Education Departments has been outlined below:

Title:	*Industrial Arts for Iowa Schools - 1969*
Cost:	$1.00
Order From:	State of Iowa Department of Public Instruction Information and Publications Service Grimes State Office Building Des Moines, Iowa 50319
Title:	*Plastics for Industrial Arts*
Cost:	Gratis to schools
Order From:	State Department of Education 120 E. Tenth Street Topeka, Kansas 66612
Title:	*Industrial Arts Handbook*
Cost:	Gratis
Order From:	James H. Disney, Supervisor Industrial Arts State Department of Education State Office Building Frankfort, Kentucky 40601
Title:	*Minnesota Industrial Arts Plastics Guide*
Cost:	$2.50
Order From:	Documents Section Room 140 Centennial Building St. Paul, Minnesota 55101
Title:	*Plastics Guide*
Cost:	
Order From:	W.D. Smith State Supervisor of Industrial Arts State Department of Education Santa Fe, New Mexico 87501

Title: *An Experimental Resource Unit in Plastics for Industrial Arts*
Cost: 74¢
Order From: Publications Distribution Unit
New York State Education Department
Albany, New York 12224

Title: *North Carolina Industrial Arts Guide*
Cost: Gratis
Order From: Consultant, Industrial Arts Education
Department of Public Instruction
State of North Carolina
Raleigh, North Carolina

Title: *Plastics as an Area of Industrial Arts Instruction*
Cost:
Order From: Mr. Earl R. Zimmerman, Coordinator
Division of Industrial Arts
Department of Education
Box 911
Harrisburg, Pennsylvania 17126

Title: *Plastics Education Guide*
Cost: $1.00
Order From: Utah State Board of Education
136 E. South Temple
1300 University Club Building
Salt Lake City, Utah 8411

Title: *Plastics Education Guide*
Cost: Gratis
Order From: State Department of Education
Cheyenne, Wyoming

Title: *Vermont Plastics Guide*
Cost: Gratis
Order From: Vermont Department of Education
Montpelier, Vermont

Title: *Plastics Guide*
Cost: Gratis
Order From: Idaho Department of Education
518 Front Street
Boise, Idaho 83702

Title: *Plastics Guide*
Cost: Gratis
Order From: Industrial Arts Education Service
State Department of Education
Richmond, Virginia 23216

b. Occupational Education Including Vocational Training, Technical Training and Two-Year College Programs - Although a certain body of content would be suitable for occupational educational programs on a universal basis, such programs should be geared directly to the needs of nearby industry within which the graduates are most likely to become employed. For this reason, educators are urged to consider seriously the advisability of developing program content through the assistance of an industrial advisory committee. The Plastics Education Foundation and local sections of the Society of Plastics Engineers can be most helpful in the identification of persons for service on such a committee. Educators considering the development of plastics education programs for occupational training purposes may solicit the helpful assistance of both the Society of Plastics Engineers and the Plastics Education Foundation by communication to 656 West Putnam Avenue, Greenwich, Connecticut 06830.

A number of course outlines from both secondary and post-secondary institutions are on file with the Plastics Education Foundation and may be obtained for review by educational institutions contemplating the development of a plastics education program.

Several institutions conduct a variety of short term courses geared to the specific needs of individuals and industry. Short term courses are also provided by proprietary schools, one of which is International Plastics Industry Consultants, Inc., P.O. Box 1324, Long Island City, New York 11101.

International Correspondence Schools, Scranton, Pennsylvania 18515, also offers a plastics technician course.

2. **College and University – Teacher Education**

The Society of Plastics Engineers Education Committee conducts a periodic survey of college level course offerings in the field of polymeric materials and has compiled a list of schools with such offerings. The 106 schools surveyed constitute the complete Engineers' Council for Professional Development list of accredited chemical engineering curricula plus several additional schools known to offer polymer courses. The complete survey of university instruction in polymeric materials may be obtained directly from the Society of Plastics Engineers.

An additional source of information relative to course offerings at the collegiate level is the annual listing of such programs in the Modern Plastics Encyclopedia. This listing includes teacher education programs as well as chemical

engineering programs and two-year college programs.

Graduate level courses in cooperation with Stevens Institute of Technology are operated by the Plastics Institute of America, a non-profit educational and research organization. Additional details concerning the Plastics Institute of America may be obtained through correspondence with the Institute at Stevens Institute of Technology, Hoboken, New Jersey 07030.

The following institutions have specially designed courses to prepare industrial arts teachers to teach plastics. In some cases, these courses would be appropriate to persons aspiring to teach plastics at occupational education levels. Interested persons are encouraged to inquire of the college or university regarding such appropriacy.

Ball State University
Industrial Arts Division
Muncie, Indiana

Industrial Arts Division
State University College
1300 Elmwood Avenue
Buffalo, New York 14222

Department of Vocational Education
New York University
Barney Building
26-36 Stuyvesant Street
New York, New York 10003

Division of Industrial Arts & Technology
State University College
Oswego, New York 13126

Department of Industrial Arts
San Diego State College
San Diego, California 92115

Department of Industrial Education
Southern Illinois University
Carbondale, Illinois 62901

Iowa State University
Ames, Iowa 50010

Morehead State University
Morehead, Kentucky 40351

Murray State University
Murray, Kentucky 42071

Department of Industrial Education & Technology
Gorham State College
Gorham, Maine 04038

Montclair State College
Upper Montclair, New Jersey 07043

Trenton State College
Trenton, New Jersey 08625

NOTE: See Bibliography in An Experimental Resource Unit in Plastics for Industrial Arts (Available from SPI)

Through arrangement with the Society of Plastics Engineers, the following Polymer Science booklist has been provided. These up-to-date publications have been classified into ten subject areas to aid individuals searching book literature in a particular field.

PLASTICS—GENERAL

Alfrey, Turner and Gurnee, E. F., *Organic Polymers,* Prentice-Hall, Inc., Englewood Cliffs, N. J. (1967).

American Chemical Society, *Addition and Condensation Polymerization Processes,* Washington, D. C. (1969).

American Chemical Society, *Cellulases and Their Applications,* Washington, D. C. (1969).

American Chemical Society, *Celluloses Plastics and Their Commercial Development,* Washington, D. C. (1969).

American Chemical Society, *Epoxy Resins,* Washington, D. C. (1970).

Andrews, E. H., *Fracture in Polymers,* American Elsevier Publishing Co., New York (1968).

Arnold, L. K., *Introduction to Plastics,* Iowa State University Press, Ames, Iowa (1968).

Beach, N. E., *Plastics Laminate Materials,* Foster Publishing Co., Long Beach, Calif. (1968).

Becker, Walter, *U.S. Sandwich Panel Manufacturing/Marketing Guide,* Technomic Publishing Co., Stamford, Conn. (1967).

Behr, Erich, *Hochtemperaturbestandige Kunststoffe,* Carl Hanser Verlag, Duesseldorf, West Germany (1969).

Benjamin, B. S., *Structural Design with Plastics* (SPE Polymer Science and Engineering Series), Van Nostrand Reinhold Co., New York (1969).

Benning, C. J., *Plastics Foams, Vol. 1; Chemistry and Physics of Foam Formation, Vol. 2: Structure Properties and Applications,* John Wiley & Sons, Inc., New York (1969).

Bovey, F. A., *Polymer Conformation and Configuration,* Academic Press, New York (1969).

Briston, J. H. and Goselin, C. C., *An Introduction to Plastics,* Philosophical Library, Inc., New York (1968).

Broutman, L. J., and Crock, R. H., eds., *Modern Composite Materials,* Addison Wesley Publishing Co., Reading, Mass. (1967).

Bruins, P. F., ed., *Plastics for Electrical Insulation,* John Wiley & Sons, New York (1968).

Bruins, P. F., ed., *Polyurethane Technology,* John Wiley & Sons, Inc., New York (1969).

Bruins, P. F., ed., *Epoxy Resin Technology,* John Wiley & Sons, Inc., New York (1968).

Buist, J. M. and Gudgeon, H., eds., *Advances in Polyurethane Technology,* John Wiley & Sons, Inc., New York (1969).

Butler, G. B. and O'Driscoll, K. F., eds., *Reviews in Macromolecular Chemistry, Vol. 1, 2, 3,* Marcel Dekker, Inc., New York (1967).

Carroll, Benjamin, ed., *Physical Methods in Macromolecular Chemistry, Vol. 1,* Marcel Dekker, Inc., New York (1969).

Crank, J. and Park, G. S., *Diffusion in Polymers,* Academic Press, New York (1968).

Davidson, R. L. and Sittig, Marshall, eds., *Water-Soluble Resins,* 2nd ed., Van Nostrand Reinhold Co., New York (1968).

Dombrow, B. A., *Polyurethanes,* 2nd ed., Van Nostrand Reinhold Co., New York (1969).

Domininghaus, Hans, *Taschenbuecher, zum Kunststofftechnik,* Carl Hanser Verlag, Duesseldorf, West Germany (1969).

Domininghaus, Hans, *Kunststoff Fibel* (in German), Zechner & Huthig Verlag, Speyer a. Rhein, West Germany (1967).

Doyle, E. N., *The Development and Use of Polyester Products,* McGraw-Hill, New York (1969).

Frank, H. P., *Polypropylene,* Gordon & Breach, New York (1968).

Gaylord, Norman, *Macromolecular Syntheses, Vol. 3,* Wiley-Interscience, New York (1969).

41545

Griff, A. L., *Plastics Extrusion Technology*, 2nd ed., Reinhold, New York (1968).

Hahn, Albert, Williams, Roger and Zabel, Herman, *The Petrochemical Industry: Markets and Economics*, McGraw-Hill, New York (1970).

Hamann, K., *Die Chemie der Kunststoffe* (in German), Walter de Gruyter & Co., Berlin, Germany (1967).

Hartsock, J. A., *Design of Foam-Filled Structures*, Technomic Publishing Co., Inc., Stamford, Conn. (1969).

Hospital Bureau, Inc., *Plastics in Hospitals*, New York (1968).

Jones, Gwendolyn, *Packaging, A Guide to Information Sources*, Gale Research Co., Detroit, Mich. (1967).

Technomic Publishing Co., Inc., *U.S. Foamed Plastics Markets and Directory*, Stamford, Conn. (1969).

Thomas Publishing Co., *The Thomas Microfile of Plastics Technology*, Thomas Publishing Co., New York (1969).

Tsai, S. W., Halpin, J. C. and Pagano, N. J., *Composite Materials Workshop* (Progress in Materials Science Series), Technomic Publishing Co., Inc., Stamford, Conn. (1967).

Tsuruta, T. and O'Driscoll, K. F., eds., *Structure and Mechanism in Vinyl Polymerization*, Marcel Dekker, Inc., New York (1969).

Whitehouse, A. A. K., Pritchett, E. G. K., and Barnett, G., *Phenolic Resins*, 2nd Ed., American Elsevier, New York (1968).

ADHESIVES

Alner, D. J., ed., *Aspects of Adhesion, Volume 4: Proceedings of the Fourth Conference on Adhesion Held at The City Univ.*, Univ. London Press, London (1968).

Cagle, C. V., *Adhesive Bonding: Techniques and Applications*, McGraw-Hill, New York (1968).

Patrick, R. L., ed., *Treatise on Adhesion and Adhesives, Vol. 2: Materials*, Marcel Dekker, Inc., New York (1969).

COATINGS

Burns, R. M. and Bradley, W. W., *Protective Coatings for Metals*, 3rd Ed., Reinhold, New York (1967).

Damusis, Adolfus, *Sealants*, Reinhold, New York (1967).

Goldie, William, *Metallic Coating of Plastics, Vols. 1 and 2*, Electrochemical Publications, Ltd., Middlesex, England (1969).

Myers, R. R. and Long, J. S., *Treatise on Coatings, Vol. 1: Film Forming Compositions, Parts I, II, III*, Marcel Dekker, New York (1967-1968).

Roberts, A. G., *Organic Coatings-Properties, Selection and Use*, U.S. Government Printing Office, Washington, D. C. (1968).

Sweeting, O. J., *The Science and Technology of Polymer Films, Vol. 1*, Wiley-Interscience, New York (1968).

Weiss, P. and Cheever, G. D., eds., *Interface Conversion for Polymer Coatings*, American Elsevier, New York (1969).

ELASTOMERS

Craig, A. S., *Dictionary of Rubber Technology*, Philosophical Library, New York (1969).

Kennedy, U. P. and Tornquist, E. G., *High Polymers, Vol. 23: Polymer Chemistry of Synthetic Elastomers, Part 1*, Wiley, New York (1968).

Keskkula, Henno, ed., *Polymer Modification of Rubbers and Plastics*, John Wiley & Sons, Interscience Div., New York (1969).

Waltz & Puget, *International Technical Guidebook for 1968, 'Europoly' Rubbers and Plastics*, Paris, France (1968).

FABRICATION

Dietz, A. G. H., *Composite Engineering Laminates*, The MIT Press, Cambridge, Mass. (1969).

Learning Systems Ltd., *The Elements of Injection Moulding of Thermoplastics*, Transatlantic Arts, Inc., New York (1968).

Pye, R. G. W., *Injection Mold Design*, Transatlantic Arts, Inc., Levittown, N. Y. (1968).

Sors, L., *Plastic Mould Engineering*, Pergamon, Long Island City, N. Y. (1967).

Wakler, J. S. and Martin, F. R., *Injection Moulding of Plastics*, Transatlantic Arts, Inc., N. Y. for The Plastics Institute, England (1967).

Zehev Tadmor and Klein, Imrich, *Plasticating Extrusion*, Van Nostrand Reinhold Co., New York (1970).

FIBERS

Frazer, A. H., ed., *High Temperature Resistant Fibers*, John Wiley & Sons, Inc., New York (1967).

Hearle, J. W. S., Grosberg, P. and Baker, S., *Structural Mechanics of Fibers, Yarns and Fabrics, Vol. 1*, Wiley-Interscience (1969).

Mark, H. F., Atlas, S. M. and Cernia, E., eds., *Man-Made Fibers: Science and Technology, Vol. 1, 2*, Wiley, New York (1968).

ION EXCHANGE

Zundel, G., *Hydration and Intermolecular Interaction (Infrared Investigations with Polyelectrolyte Membranes)*, Academic Press, New York (1969).

RHEOLOGY

Andrews, R. D. and Eirich, F. R., *High Speed Testing—Vol. 6; Vol. 7: The Rheology of Solids*, John Wiley & Sons, Interscience, New York (1967), (1969).

Ferry, J. D., *Viscoelastic Properties of Polymers*, Wiley-Interscience (1970).

C. INDUSTRY LITERATURE

There is a wealth of valuable information available from raw materials supplier and equipment manufacturers in the form of company literature. Trade and professional associations, listed in Section III of this guide, are another excellent literature source.

The following listing indicates the wide range of data available from some of the companies in the plastics industry and is not intended to be complete or represent every possible category. Most of this literature is available free of charge.

THE ABC's OF MODERN PLASTICS (35 pages)
Union Carbide Corporation
Plastics Division
270 Park Avenue
New York, New York 10017

Describes basic plastics materials, their sources and applications.

THE ANATOMY OF PLASTICS
Science & Technology
205 E. 42nd Street
New York, New York

BLOW MOLDING - AN OPERATING MANUAL (72 pages)
U.S. Industrial Chemicals
99 Park Avenue
New York, New York 10016

Describes the blow molding process, particularly with polyethylene emphasizing start up and shut down of operations as well as specific problem areas.

BLOW MOLDING FORTIFLEX POLYETHYLENE, BULLETIN 3PC (32 pages)
Celanese Plastics Company
550 Broad Street
Newark, New Jersey 07102

BLOW MOLDING OF ALATHON POLYOLEFIN RESINS (29 pages)
Polyolefins Division
Plastics Department
E.I. DuPont de Nemours Company
Wilmington, Delaware 19898

BLOW MOLDING OF BAKELITE POLYETHYLENES (28 pages)
Union Carbide Corporation
Plastics Products
270 Park Avenue
New York, New York 10017

BLOW MOLDING POLYETHYLENE (24 pages)
Dow Chemical Company
Plastics Department
Midland, Michigan

CELLULOSE ACETATE BUTYRATE FOR PROTECTIVE COATINGS
Eastman Chemical Products, Inc.
Kingsport, Tennessee 37662

COLORING PLASTICS (40 pages)
Ferro Corporation
4150 East 56th Street
Cleveland, Ohio 44105

A compilation of a number of articles prepared on the subject of coloring all types of thermoplastic and thermosetting materials.

DESIGN GUIDE
Security Plastics, Inc.
4297 E. 11th Avenue
Hialeah, Florida 33013

DESIGNING WITH RIGID VINYL
B.F. Goodrich Chemical Company
3135 Euclid Avenue
Cleveland, Ohio 44115

DUPONT MAGAZINE
Editor
DuPont Magazine
Wilmington, Delaware 19898

ENGINEERING PLASTICS AND DESIGN, BULLETIN G1B
Celanese Plastics Company
550 Broad Street
Newark, New Jersey 07102

ENGINEERING WITH SILASTIC SILICONE RUBBER

Dow-Corning Corporation
Midland, Michigan 48640

ENJAY MAGAZINE
Enjay Chemical Company
60 W. 49th Street
New York, New York 10020

EXTRUSION, BULLETIN N3A and BULLETIN A3C
Celanese Plastics Company
550 Braod Street
Newark, New Jersey 07102

C552

A FACTORY ENGINEERING AND TECHNOLOGY REPORT
PLASTICS #19
Readers Service Department
Factory
330 W. 42nd Street
New York, New York

FIBERGLAS REINFORCED PLASTICS
Owens-Corning Fiberglas Corporation
Appliance Materials Division
Industrial Materials Division
Toledo, Ohio 43602

FILAMENT WINDING WITH EPOXY RESIN SYSTEMS
CIBA Products Company
Division of CIBA Corporation
Fairlawn, New Jersey

FOURTEEN NEW DESIGNS IN SHELL PLASTICS AND RESINS
Shell Chemical Company
Plastics and Resins Division
110 W. 51st Street
New York, New York

GLOSSARY OF PLASTICS TERMS (36 pages)
Phillips Petroleum Company
Chemical Department - Plastics Division
Bartlesville, Oklahoma 74004

A glossary of terminology used in the plastics industry.

HOW TO CHOOSE AN EXTRUDER (107 pages)
Prodex Corporation
Fords, New Jersey 08863

Indicates important criteria in selecting an extruder with a basic description of the extruder and its component parts.

INJECTION MOLDING TECHNOLOGY (12 pages)
The Dow Chemical Company
Plastics Division
Midland, Michigan 48640

Describes injection molding, the machine and the problems.

"INPLANT TRAINING BOOKLETS"
The Society of the Plastics Industry
250 Park Avenue
New York, New York 10017

Pocket size booklets give sound "how to" information on operating plastics machinery and other subjects. Basic data useful for students and new employees.

- Compression and Transfer Molding (20 pages)
- Extrusion
- Injection Molding (15 pages)
- Finishing and Decorating (35 pages)

S 553

THE MARBON FAMILY OF ABS DESIGN ENGINEERING MATERIALS
Marbon Chemical Company
P.O. Box 68
Washington, West Virginia 26181

MATERIALS NEWS FROM DOW-CORNING
Dow-Corning Corporation
Midland, Michigan 48640

PAINTING PLASTICS MANUAL (77 pages)
Bee Chemical Company
2700 East 170th Street
Lansing, Illinois 60438

A comprehensive manual describing a variety of decorating, finishing and marketing operations.

PETROTHENE POLYOLEFINS (a processing guide) (140 pages)
U.S. Industrial Chemicals Co.
99 Park Avenue
New York, New York 10016

A guide to processing of polyolefins describing molecular porperties of resins, additives, and the techniques of processing including extrusion, calendering, injection molding, blow molding, thermoforming, and compression molding.

POLYETHYLENE EXTRUSION COATING - AN OPERATING MANUAL
U.S. Industrial Chemicals Company
99 Park Avenue
New York, New York 10016

STANDARD TESTS ON PLASTICS (61 pages)
Celanese Plastics Company
744 Broad Street
Newark, New Jersey

Describes the significant tests performed on plastics and their importance.

THE STORY OF THE PLASTICS INUDSTRY
The Society of the Plastics Industry
250 Park Avenue
New York, New York 10017

Provides basic information (in layman's language) about the history of plastics, industry's growth, plastics raw materials - typical end used with illustrations, properties, methods of processing and fabricating.

THERMOFORMING (24 pages)
Celanese Plastics Company
744 Broad Street
Newark, New Jersey

Analyzes the basic thermoforming techniques available to the processor with advantages and disadvantages as well as problem solving sections.

ULTRASONIC ASSEMBLY
Branson Sonic Power Company
Danbury, Connecticut

UREA AND ALKYD MOLDING COMPOUNDS (46 pages)
Allied Chemical Corporation
Plastics Division
P.O. Box 365
Morristown, New Jersey

A description of compression and transfer molding with emphasis on the amino plastics.

D. OTHER SOURCES

Title: *A Resource Unit for Teaching Plastics Technology at the Collegiate Level*
Author: James R. Harty, 460 36th Avenue, San Francisco State College, San Francisco, California

Title: *A Guide to Plastics in the Industrial Arts Program of the Academic High Schools of New York City*
Author: Arthur E. Golomb
Publisher: Dissertation abstracts, Volume XXIV, No. 4, 1963, order 635374, University Microfilms, Inc., 313 North 1st Street, Ann Arbor, Michigan, 48103

Title: *A Study of the Industry and Field of Plastics as a Creative Medium*
Author: Robert Lloyd Cantor
Publisher: Order 5412, University Microfilms, Inc., 313 North 1st Street, Ann Arbor, Michigan 48103
Description: Doctoral thesis

Title: *Plastics Technology and Its Reflection in Industrial Arts Teacher-Education Programs*
Author: James J. Runnals
Publisher: University of Missouri, University Terrace, Columbia, Missouri
Description: Doctoral dissertation

III. Trade and Professional Associations

There are a number of trade associations and professional/technical societies in the plastics and related industries. Some of these are listed below and can provide the educator with a wealth of information.

American Chemical Society
1155 Sixteenth Street, N.W.
Washington, D.C.

American Institute of Chemical Engineers
345 East 47th Street
New York, New York 10017

American Petroleum Institute
1271 6th Avenue
New York, New York

American Society of Tool and Manufacturing Engineers
10700 Puritan Avneue
Detroit, Michigan

Manufacturing Chemists' Association
1825 Connecticut Avenue, N.W.
Washington, D.C.

National Association of Plastic Fabricators
1108 Standard Building
Cleveland, Ohio

Plastics Education Foundation
656 W. Putnam Avenue
Greenwich, Connecticut 06830

Society of Plastics Engineers, Inc.
656 W. Putnam Avenue
Greenwich, Connecticut 06830

The Society of the Plastics Industry, Inc.
250 Park Avenue
New York, New York 10017

The Society of the Plastics Industry (Canada), Inc.
600z Eglinton Avenue, East
Toronto, Ontario, Canada

The Society of the Plastics Industry, Inc.
Western Section
611 South Catalina Street
Los Angeles, California 90005

Technical Association of The Pulp and Paper Industry (TAPPI)
360 Lexington Avenue
New York, New York 10017

Vinyl Fabrics Institute
60 East 42nd Street
New York, New York 10017

IV. Equipment

Equipment used in the presentation of plastics courses can be classified as either laboratory/testing or production equipment. The companies listed in this section are in part those which is response to a questionnaire from the SPI, indicated they have equipment which may be used in the educational field. However, there are other machinery manufacturers listed in the SPI Membership Directory and other reference sources which should be contacted for details on their equipment as well as prices.

Pages 44 - 45 list equipment which the University of the State of New York suggests for industrial arts courses.

Consultant assistance relative to equipment selection is available upon request to the Plastics Education Foundation.

A. LABORATORY/TESTING EQUIPMENT

ABRASION TESTING EQUIPMENT

Taber Instrument Company
111 Goundry Street
North Tonawanda, New York 141514151

GEL TIMER

C.W. Brabender Instruments, Inc.
50 East Wesley Street
South Hackensack, New Jersey 07606

Mol-Rez Division - Sub. of Whittaker Corp.
American Petrochemical Corporation
3134 California Street, N.E.
Minneapolis, Minnesota 55418

MELT INDEXER

D & R Plastic Welders, Inc.
Box J
Hazardville, Connecticut

Custom Scientific Company
541 Devon Street
Kearney, New Jersey 07032

F.F. Slocomb Corporation
100 Poplar Street
P.O. Box 1591
Wilmington, Delaware 19899

PHYSICAL PROPERTIES TESTING EQUIPMENT

American Chain & Cable Company, Inc.
Wilson Mechanical Instrument Division
230 Park Avenue
New York, New York 10017

D & R Plastic Welders, Inc.
Box J
Hazardville, Connecticut

C.W. Brabender Instruments, Inc.
50 East Wesley Street
South Hackensack, New Jersey 07606

W.C. Dillon & Co., Inc.
14620 Keswick Street
Van Nuys, California 91405

Instron Engineering Corporation
2500 Washington Street
Canton, Massachusetts 02021

Tinius Olsen Testing Machine Company
500 North 12th Street
Philadelphia, Pennsylvania 19123

VISCOSITY MEASURING DEVICES

C.W. Brabender Instruments, Inc.
50 East Wesley Street
South Hackensack, New Jersey 07606

Brookfield Engineering Laboratories, Inc.
240 Cushing Street
Stoughton, Massachusetts 02072

The Martin Sweets Company, Inc.
3131 West Market Street
Louisville, Kentucky 40212

WEATHERING EQUIPMENT

Atlas Electric Devices Company
4114 North Ravenswood Avenue
Chicago, Illinois 60613

D & R Plastic Welders, Inc.
Box J
Hazardville, Connecticut

B. PRODUCTION EQUIPMENT

BLOW MOLDING EQUIPMENT

Beloit Corporation
Washington & Green Streets
Downington, Pennsylvania 19335

Farrel Canada Limited
280 Belfield Road
Rexdale, Ontario, Canada

Farrel Co. - Division of USM Corp.
Plastics Molding Machinery Division
565 Blossom Road
Rochester, New York 14610

Improved Machinery, Inc. - Sub. of Ingersoll-Rand Co.
150 Burke Street
Nashua, New Hampshire 03060

Modern Plastic Machinery Corporation
64 Lakeview Avenue
Clifton, New Jersey 07015

Stokes Division
Pennsalt Corporation
5500 Tabor Road
Philadelphia, Pennsylvania 19120

Strong Plastics, Inc. - Sub. of Republic Corp.
700 Lamport Street
Elsegundo, California 90245

Technical Machinery Corporation
68 Newton Plaza (Engineers Hill)
Plainview, L.I., New York

Waldron-Hartig Division
Midland-Ross Corporation
P.O. Box 791
New Brunswick, New Jersey 08903

CALENDERING EQUIPMENT

Adamson United Company
Sub. United Engineering & Foundry Co.
730 Carroll Street
Akron, Ohio 44304

Canada Machinery Corporation Limited
19 Concession Street
Galt, Ontario, Canada

0561

Farrel Canada Limited
280 Belfield Road
Rexdale, Ontario, Canada

Farrel Corporation
Ansonia, Connecticut 06401

COMPRESSION AND LAMINATING PRESSES

Fred S. Carver Hydraulic Equipment
5 Chatham Road
Summit, New Jersey 07901

Dake Corporation
641 Robbins Road
Grand Haven, Michigan 49417

Farrel Canada Limited
280 Belfield Road
Rexdale, Ontario, Canada

Farrel Co.- Div. of USM Corp.
Plastics Molding Machinery Division
565 Blossom Road
Rochester, New York 14610

HPM Division
Koehring Company
820 Marion Road
Mount Gilead, Ohio 43338

C.A. Litzler Co., Inc.
4800 W. 160th Street
Cleveland, Ohio 44135

Pasadena Hydraulics, Inc.
200 N. Berry Street
Brea, California 92621

Stokes Division
Pennsalt Corporatin
5500 Tabor Road
Philadelphia, Pennsylvania 19120

CONVEYORS AND DRYERS

Ball & Jewell Company, Inc.
Division of Beloit Eastern Corporation
22 Franklin Street
Brooklyn, New York 11222

Conair, Inc.
Conair Building
Franklin, Pennsylvania 16323

Foremost Machine Builders, Inc.
23 Spielman Road
Fairfield, New Jersy 07006

Vac-U-Mac
227 Main Street
Belleville, New Jersey 07109

Whitlock, Inc.
23231 Industrial Park Drive
Farmington, Michigan 48024

CUTTING EQUIPMENT

Foster & Allen, Inc.
26 Commerce Street
Box 466
Chatham, New Jersey 07928

Viking-Chase Ltd., Inc.
36th Street and A.V.R.R.
Pittsburgh, Pennsylvania 15201

ELECTRONIC HEATERS

W.T. LaRose & Associates, Inc.
Box F, Lans Station
Troy, New York 12182

Votator Division
Chemetron Corporation
P.O. Box 43
Louisville, Kentucky 40201

ELECTROSTATIC EQUIPMENT

The Simco Company, Inc.
920 Walnut Street
Lansdale, Pennsylvania 19446

ENGRAVING EQUIPMENT

New Hermes Engraving Machine Corp.
154 West 14th Street
New York, New York 10011

EXPANDABLE POLYSTYRENE MOLDING EQUIPMENT

Conair, Inc.
Conair Building
Franklin, Pennsylvania 16323

Crown Machine & Tool, Co.
840 Great Southwest Parkway
P.O. Box 610
Arlington, Texas 76011

EXTRUSION EQUIPMENT

A-Be Industries, Inc.
16633 Minnesota Avenue
Paramount, California 90723

Barnett J. Danson & Associates Limited
33 Railside Road
Don Mills, Ontario, Canada

Beloit Corporation
Washington & Green Streets
Downington, Pennsylvania 19335

The Black Clawson Company
Plastics Department
Extrusion Equipment
2nd & Vine Streets
Hamilton, Ohio 45011

C.W. Brabender Instruments, Inc.
50 East Wesley Street
South Hackensack, New Jersey 07606

David-Standard
Division of Crompton & Knowles Corporation
U.S. Route 1
Pawcatuck, Connecticut 02891

Egan Machinery Company
36 South Adamsville Road
Somerville, New Jersey 08876

Gatto Machinery Development Corporation
134 Rome Street
Farmingdale, L.I., New York 11735

Killion Extruders, Inc.
56 Depot Street
Verona, New Jersey 07044

Miller Industries
Div. The Elkhart Bridge & Iron Company
1227 W. Beardsley Avenue, P.O. Box 823
Elkhart, Indiana 46514

Modern Plastic Machinery Company
Sub. of Savoy Ind., Inc.
64 Lakeview Avenue
Clifton, New Jersey 07015

NRM Corporation - Sub of AMK Corp.
47 West Exchange Street
Akron, Ohio 44308

564

Rainville Co. Inc. (The)
200 Clay Ave.
Middlesex, N.J. 08846

Reifenhauser U.S. Sales Corp.
535 N. Midland Avenue
Saddle Brook, New Jersey 07662

Francis Shaw (Canada) Ltd.
1393 Grahams Lane - P.O. Box 158
Burlington, Ontario, Canada

Sterling Extruder Corporation
901 Durham Avenue
So. Plainfield, New Jersey 07080

Stokes Division
Pennsalt Corporation
5500 Tabor Road
Philadelphia, Pennsylvania 19120

Technical Machinery Corporation
68 Newton Plaza (Engineers Hill)
Plainview, L.I., New York

Waldron-Hartig Division
Midland-Ross Corp.
P.O. Box 791
New Brunswick, New Jersey 08903

Welding Engineers, Inc.
P.O. Box 391
Norristown, Pennsylvania 19404

EXTRUSION ACCESSORY EQUIPMENT

A-Be Industries, Inc.
16633 Minnesota Avenue
Paramount, California 90723

Conair, Inc.
Conair Building
Franklin, Pennsylvania 16323

Gatto Machinery Development Corporation
134 Rome Street
Farmingdale, L.I., New York 11735

FOAM DISPENSING EQUIPMENT

Admiral Equipment Corp.
305 W. North Street
Akron, Ohio 44303

Binks Manufacturing Company
3114 West Carroll Avenue
Chicago, Illinois 60612

Finn and Fram, Inc.
8400 San Fernando Road
Sun Valley, California 91352

Glas-Craft of California - Div. of Republic Corp.
9145 Glen Oaks Boulevard
Sun Valley, California 91352

Lemco-Jennings
3252 Monroe Street
Toledo, Ohio 43606

The Martin Sweets Company, Inc.
3131 West Market Street
Louisville, Kentucky 40212

Park-Hannesson Ltd. - Div. of MIA Chemical Co.
813 Henry Avenue, P.O. Box 862
Winnipeg, Manitoba, Canada

Sealzit Division
The Flintkote Company
4075 Main Street, Suite 600
Riverside, California 92501

Viking-Chase Ltd., Inc.
36th Street and A.V.R.R.
Pittsburgh, Pennsylvania 15201

FILAMENT WINDING EQUIPMENT

McClean-Anderson, Inc.
120 West Melvina Street
Milwaukee, Wisconsin 53212

GRANULATING & PELLETIZING EQUIPMENT

Cumberland Engineering Company, Inc.
P.O. Box 6065
Providence, Rhode Island 02904

Entoleter, Inc. - Sub. of American Mfg. Co., Inc.
251 Welton Street
Hamden, Connecticut 06511

Flinchbaugh Products, Inc.
Div. Gulf & Western Ind. Inc.
P.O. Box 127, Redco Avenue
Red Lion, Pennsylvania 17356

GRINDING EQUIPMENT

Ball & Jewell Company, Inc.
Division of Beloit Eastern Corporation
22 Franklin Street
Brooklyn, New York 11222

Foremost Machine Builders, Inc.
23 Spielman Road, P.O. Box 644
Fairfield, New Jersey 07006

HOT STAMPING PRESS

The Acromark Company
60 Locust Avenue
Berkeley Heights, New Jersey 07922

Apex Machine Company
3000 N.E. 12th Terrace
Fort Lauderdale, Florida 33308

Franklin Manufacturing Corporation
692 Pleasant Street
Norwood, Massachusetts 02062

Howmet Corporation
Roll Leaf Division
4511 New York Avenue
Union City, New Jersey 07887

Kensol-Olsenmark, Inc.
30 Melville Park Road
Melville, L.I., New York 11746

INJECTION MOLDING EQUIPMENT

Barnett J. Danson & Associates Limited
1840 Birchmount Road
Scarborough, Ontario, Canada

Battenfeld Corporation of America
7301 North Monticello Avenue
Skokie, Illinois 60613

Beloit Corporation
Washington & Green Streets
Downington, Pennsylvania 19335

Farrel Canada Ltd.
280 Belfield Avenue
Rexdale, Ontario, Canada

Farrel Co. - Div. of USM Corp.
Plastics Molding Machinery Division
565 Blossom Road
Rochester, New York 14610

Flinchbaugh Products, Inc. - Sub. of Gulf & Western Ind. Inc.
P.O. Box 127, Redco Avenue
Red Lion, Pennsylvania 17356

Hinchman Manufacturing Company, Inc.
259 East First Avenue
Roselle, New Jersey 07203

HPM Division
Koehring Company
820 Marion Road
Mount Gilead, Ohio 43338

Husky Manufacturing & Tool Works Ltd.
200 Bentworth Avenue
Toronto, Ontario, Canada

Improved Machinery, Inc. - Sub of Ingersoll & Rand Co.
150 Burke Street
Nashua, New Hampshire 03060

Lombard Industries, Inc. - Sub. of USM Corp.
50 Main Street
Ashland, Massachusetts 01721

Modern Plastic Machinery Corporation - Sub. of Savoy Ind., Inc.
64 Lakeview Avenue
Clifton, New Jersey 07015

Nassau Manufacturing Co., Inc.
923 Old Nepperhan Avenue
Yonkers, New York 10703

The New Britain Machine Company - Div. of Litton Ind.
Plastics Machine Division
South Street
New Britain, Connecticut 06050

Newbury Industries, Inc.
10975 Kinsman Road
Newbury, Ohio 44065

Polymer Machinery Corp.
Plastic Processing Equipment
60 Woodlawn Road
Berlin, Connecticut 06037

Reed-Prentice Division
Package Machinery Company
330 Chestnut Street
East Longmeadow, Massachusetts 01028

Simplomatic Manufacturing Company
4416 West Chicago Avenue
Chicago, Illinois 60551

Standard Tool Company
217 Hamilton Street
Leominster, Massachusetts 01453

Stokes Division
Pennsalt Corporation
5500 Tabor Road
Philadelphia, Pennsylvania 19120

Trueblood, Inc.
6891 Cobaugh Road
Tipp City, Ohio 45371

MILLING EQUIPMENT

The Black Clawson Company
Hamilton Division
Plastics Department
2nd & Vine Streets
Hamilton, Ohio 45011

MIXING

C. REPRESENTATIVE SCHOOL EQUIPMENT

Suggested for Junior and Senior High School
Industrial Arts Courses
by
The State Education Department
Bureau of Industrial Arts Education
Albany, New York 12224

Description	
1/5 ounce or larger injection molding machines	Jr. & Sr. High
12 ton or larger capacity, compression/laminating press complete with heated and cooled platens, facing sheets for laminating, thermometers and 1 compression mold, etc.	Jr. & Sr. High
Vacuum former 7"x7" with vacuum source and heating unit	Junior High
Vacuum former 10"x14" with vacuum source and heating unit	Junior High
Portable Scrap Granulator 7"x6½" throat or larger capacity with 1 Hp motor and switch	Senior High
Vacuum, pressure and mechanical former 18" x18" with heating unit, material clamping device, vacuum and pressure sources	Senior High
Vacuum former, 10"x14" with vacuum source and heating unit	Senior High
Electric oven and burner unit, electric kitchen stove with large oven and four surface cooking units, 30"x40" with wide oven or equal OR	Jr. & Sr. High
Hot air oven, thermostatically controlled, 450° or higher maximum temperature, interior minimum dimensions 26" wide by 20" high by 20" deep - Model 51-550 or equal	Jr. & Sr. High
Heat Sealer, Hand Operated	Jr. & Sr. High
Plastic welding unit, hand operated, kit with extra tips, etc.	Jr. & Sr. High
Engraving machine	Senior High
Hot stamping machine	Senior High
Thermometer, 6" shank, dial face reading type 100°F to 600°F	Jr. & Sr. High
Pressure cooker, 10 qt. or larger	Jr. & Sr. High

Air pressure regulators, 1 to 100 psi., single stage, spray painting type	Jr. & Sr. High
Air compressor - capacity at least equal to the air consumption of two air operated injection molders with necessary valves, hose, quick connectors	Jr. & Sr. High
Air line oilers for injection molders	Jr. & Sr. High
Postal scales, 2 lbs., capacity, spring type for weighing materials	Jr. & Sr. High
Electroplating unit, 5 amp. capacity or larger power unit and plating equipment and chemical set	Jr. & Sr. High

OPTIONAL EQUIPMENT

Extruder, laboratory type, ¾" screw or larger 20:1 screw dia. to screw length ratio	Senior High
Blow molding attachment for plastics extruder, air operated, mold closure device	Senior High
Rotational molding machine, Laboratory model	Senior High
Set testing equipment - tests for tensile compression, shear, transvers, hardness, modulus of elasticity	Senior High
All materials spray gun, for spraying plaster, plastic resins and rubber, with extra nozzles, cups, lids and hose	Senior High
Portable Plastics School consists of 16 volumes: Each volume contains raw materials and finished product samples held in place by flexible bands for removal and inspection. Multicolored charts show the method of polymerization starting from the basic raw materials and also the various methods of producing finished articles. The Commentary volume gives a brief history of each material, raw materials production, production of the plastic materials, properties, processing methods and applications.	Senior High

D. TEACHING AIDS

A variety of teaching aids have become available in the recent past. Many of these are applicable to industrial arts and occupational education programs at both the secondary and post-secondary educational levels.

The Thiokol Chemical Company, which had contracted with the Office of Economic Opportunity, Job Corps, for the operation of a Job Corps Center in the State of Utah, has developed a number of teaching aids originally for use in a plastics training program at that Center but now to be distributed nationally. Teaching aids include working plastic models of processing equipment. Additional details may be obtained from Thiokol Chemical Company, Clearfield, Utah.

The PLASTICS SCHOOL, a description of which is contained in the optional equipment listing on page 45, can be obtained from Brodhead-Garrett Company, 4560 E. 71st Street, Cleveland, Ohio 44105, or Cope Plastics Illinois, Inc., 1111 West Delmar Avenue, Godfrey, Illinois 62035.

A programmed instruction book entitled, *Fundamentals of Plastics,* obtainable from the Penton Education Division, Penton Publishing Company, Cleveland, Ohio 44113.

Transparencies - A series of Plastics processing and basic chemistry transparencies can be obtained from DCA Educational Products, 4865 Stenton Avenue, Philadelphia, Pennsylvania 19144.

Films - A number of industry produced films are available for educational purposes on a loan basis. A convenient guide to such films is the SPI Film Catalogue available from The Society of the Plastics Industry, Inc., 250 Park Avenue, New York, New York 10017.

Career Film - The Plastics Education Foundation has produced a career guidance film, How to Crack the Establishment, suitable for use at the secondary school level. Distribution of this movie through the Plastics Education Foundation.

A number of film strips and accompanying records suitable for use at early secondary or secondary school level can be obtained from the Henry Company, Kitco Division, 6405 E. Kellogg Street, Wichita, Kansas.

SELECT-A-BOX is a kit containing samples of a variety of plastics materials in several forms together with accompanying data concerning the suitability of a variety of plastics to particular applications. Advantages as well as disadvantages are listed for each material. This kit may be purchased from Edison Technical Services, Inc., 70 Riverside Drive, New York, New York 10024.

Films - Closed loop, single concept, 8mm films, Sterling Educational Films, Inc., 241 E. 34th Street, New York, New York 10016.

Plastic Education System: includes
- student experiment workbook
- teacher guide
- student tests
- course outline
- filmstrips correlated with lessons
- reference lists
- hardware
- supplies

one week teacher education workshop may be purchased from PLASTIK-LABS, Post Office Box 18011, Wichita, Kansas 67218

E. SUPPLY SOURCES

The following firms currently list supplies and/or equipment appropriate to industrial plastics instruction at secondary or post-secondary levels in both industrial arts and occupational education programs.

Brodhead-Garrett Company
4560 E. 71st Street
Cleveland, Ohio 44105

Cope Plastics Illinois, Inc.
1111 West Delmar Avenue
Godfrey, Illinois 62035

Plastic Products Company of Utah
P.O. Box 1415
Salt Lake City, Utah 84110

Industrial Arts Supply Company
1408 West Lake Street
Minneapolis, Minnesota 55408

Hastings Plastics
1704 Colorado Avenue
Santa Monica, California 90404

Teacher's Handbook, Distributive Education.

Mississippi State Dept. of Education, Jackson. Div. of Vocational and Technical Education.
MF AVAILABLE IN VT-ERIC SET.
PUB DATE - ND 47p.

DESCRIPTORS - *DISTRIBUTIVE EDUCATION; *PROGRAM GUIDES; COOPERATIVE EDUCATION; *PROGRAM PLANNING; INSTRUCTOR COORDINATORS; ADULT EDUCATION; SECONDARY EDUCATION; *TEACHER ROLE; ADVISORY COMMITTEES; YOUTH CLUBS; PROGRAM EVALUATION; *MANUALS; ADMINISTRATION; EDUCATIONAL OBJECTIVES; EDUCATIONAL PHILOSOPHY

ABSTRACT - Developed as a reference manual for both instructor coordinators and administrators, this handbook presents ideas regarding the aims, policies, organization, and operation of local programs in distributive education (DE). Among the 12 sections of this handbook are the following: (1) Types and Operation of DE Programs, (2) Methods In Selection of Student-Learner, (3) Advantages and Values of The Cooperative Part-time Program, (4) Duties and Functions of a DE Coordinator, (5) The Local Advisory Committee, (6) Criteria for Evaluating a Distributive Education Program, and (7) Distributive Education Forms. This handbook should be of interest to those planning and evaluating DE programs as well as to those operating existing programs. (JS)

FOREWORD

The primary purpose of this publication is to serve as a reference for both the new and experienced teacher-coordinator in solving many of their problems in the Distributive Education program. It may prove most helpful as other means of presenting the "Distributive Education Story".

This publication was prepared also to meet the continued demand from school administrators and from people in the field of distribution for statements regarding the aims, policies, organization, and operation of local programs of distributive education.

Grateful acknowledgement is given to former graduates and Mr. E. F. Mitchell, Head, Industrial Education, in the preparation of this publication. It is hoped that this information will assist those who wish to further expand opportunities in their communities for training both high school students and adults for occupations in the fields of marketing and distribution.

PART I

Philosophy of Distributive Education

Distributive Education, a reimbursable program in Vocational Education, is designed to prepare students for employment in the field of marketing and distribution. The scope is broad including areas in the fields of retail, wholesale, and service areas.

Distributive Education came into existence with the passage of the George-Deen Act in 1936, and received further support from the George-Barden Act of 1946. Under the provisions of this Act, Distributive Education courses in the part-time cooperative and evening classes must be of such a nature as to:

1. Increase the skills, knowledge, and ability of trainees who are employed in a apecific distributive occupation.

2. Prepare trainees in a distributive occupation for changing to a related kind of experience in another distributive occupational level.

Part-time Distributive Education classes are organized and conducted on a cooperative basis - school and business. Entrance into classes giving instruction in distributive education is confined to persons who want, need, and can profit by it through special aptitude, skills, and interest. The student who enrolls must be at least sixteen years of age or older.

Distributive Education, a vital part of the total program, makes a worthwhile contribution toward the development of good citizens, including economic, cultural, and social interests.

Although Distributive Education classes primarily terminal in nature, the student is well qualified to enter college to further his career.

With the awareness on the part of school administrators of the vast number of people employed in marketing and distribution, and its demand for better trained distributive workers, we can look to the future with greater satisfaction that progress shall continue in the Secondary Schools of Mississippi. We can be assured also, that such schedule and curriculum adjustments that are necessary, both in the educational training and laboratory experience, shall be made.

PART II

Occupational Levels of Jobs Which May Be Included In Distributive Education

1. Distributive Occupations Defined.

Distributive occupations are those followed by workers directly engaged in merchandising activities, or in contact with buyers and sellers when:

a. distributing to consumers, retailers, jobbers wholesalers and others the products of farm and industry, or selling services.

b. managing, operating or conducting a retail, wholesale, or service business.

This training applies to training given to in-school youth and to adults eligible for training in distributive education.

2. Potentials In Occupational Objectives.

One interpretation is that there should be opportunity for advancement within the firm considered as a training establishment. Another interpretation is that the training provided by the firm under consideration should develop the student's potential ability to a point where he would be occupationally competent in that particular field of distribution, even though the manager might not be able to employ the student full time after graduation.

3. Job Training Requirements.

Not only should the student's classroom experience but the on-the-job training should be of sufficient stature to justify two credits per year. Some jobs, though distributive, are <u>not</u> important or complex enough to provide sufficient training opportunities.

Example: In variety stores the type of limited "work experience" can seldom, if ever, justify classroom training or supervision. Male students' opportunities far exceed the female student in this area. Male trainees often become managers and regional managers.

Distributive Education is not a "work" program - it is an educational training program.

4. Work Environment.

The coordinator should always be alert to the environment in which the student is placed. The business should be a distributive and reputable one, the management should be respected, and the moral climate should be good. The coordinator should assure himself that working conditions are satisfactory, and good atmosphere for training does exist.

5. Progression and Rotation.

In a training program, the student-learner progresses from simple jobs to more difficult ones, this should certainly be true in a distributive occupation training program. The idea of progression must be sold to insure job potentials for the student and to insure good training. Example: In a men's department store, rotations could mean the student starts work in receiving and marking, progresses to selling men's furnishings, progresses to selling men's shoes, progresses to other departments, and then, perhaps, to some junior executive level.

There follows a listing of training establishments which normally provide good training possibilities:

1. Shoe Store
2. Women's Specialty Shop
3. Furniture Stores
4. Department Stores
5. Dry Goods - General Mdse. Stores
6. Family Clothing Stores
7. Women's Ready-To-Wear
8. Infant's Wear Shop
9. Household Appliance
10. Floor Covering, Drapes, Glassware
11. Music Stores
12. Grocery
13. Auto Accessory
14. Lumber Yard - Building Material
15. Heating, Plumbing, Paint, Glass, Wallpaper Supplies
16. Meat Markets
17. Fruit Stores
18. Hardware
19. Farm Implement
20. Jewelry
21. Hay, Grain, Seed
22. Farm - Garden Supplies
23. Drug Stores
24. Book - Stationery
25. Newspaper Circulation
26. Gift Shop
27. Office Supply
28. Camera - Photo Shop
29. Sporting Goods
30. Florist
31. Other Retail Stores
32. Wholesale Outlet in any of the above.

PART III

Types and Operation of Distributive Education Programs

High School

Cooperative part-time programs consist of students who spend part of the day in the secondary school and a part of the day in a selected distributive occupation, thereby learning a vocation through the cooperative effort of the school and community.

Post High School

The scheduling of this program is the same as the high school program, except the student, usually, is preparing for mid-management or supervision in the field of marketing and distribution.

Adults

Adult classes are those conducted during the non-working hours of the enrollees. Persons enrolled in such classes must be employed in a distributive occupation. Instruction in such classes must be supplementary to the daily employment of those enrolled.

Operation

The co-operative part-time program may be set up to offer either two (2) years training with one (1) hour per day devoted to related instruction or one (1) year of training with two (2) hours per day devoted to related instruction. Student-learners will be employed a minimum of three (3) hours per day and not less than fifteen (15) hours per week. A training agreement between the school and employer and a detailed schedule of processes based on an analysis of the occupation are required for each student.

General Areas of Instruction

A cooperative Distributive Education program involves a variety of instruction. The organized classroom instruction, on-the-job experiences, and D. E. Club activities provide opportunities which enable the student

to channel his efforts toward the accomplishment of his ultimate goal. The program develops a well adjusted individual who recognizes his responsibilities. Individual instruction in school and on-the-job is most important in developing a strong Distributive Education Program.

Group instruction involves broad general content including: a study of the social and economic changes in the local community; a study of the kinds of organizations which perform distributive functions; a study of the process of getting goods from the producer to the consumer; a study of marketing, including buying, selling, pricing, wholesaling and retailing; a study of population changes, international problems, and government regulations; a study of financial aspects of distribution including records, customer service, advertising, display, and a study of the consumer in relation to the marketing process.

PART IV

Methods In Selection of Student-Learners

1. Information on Student and his Potentials.

Determining the ability of each enrollee in the Distributive Education program is not the sole responsibility of the teacher-coordinator. The assistance of the guidance counselor, school principal, and possibly members of the advisory committee can be most helpful, all of them should be in accord with the local policy on selection of students. Students must be legally employed in the distributive occupation for which training is provided. The Memorandum of Training service as evidence of legal employment.

Through a battery of tests much information can be gathered and should be carefully analyzed relative to:

a. interest
b. ability to learn
c. aptitudes
d. personality

A student in Distributive Education must be in good physical condition which may be determined by an interview, observation, school records, and conferences with parents, teachers, and physicians.

Past achievements of the students are of special significance in the development of any and all talents which lead to well-rounded, well-adjusted citizens of the community.

There is no factor in the student's life that plays a more vital part in the student's progress and achievement than his home life. It is one of the duties of the teacher-coordinator to visit the student's home before approving his application in order that he may thoroughly understand the home environment and conditions.

A. Matching the Student to the Job.

The coordinator in search for the opportunity which will result in a successful career for the student realizes that the interest of the employer and

the student are the same. The employer is looking for a student who will be successful in the job he has to offer. The student is looking for that job in which he can succeed.

Matching a student and a job is most important!

2. Locating Training Placements

The coordinator may have difficulty in determining proper placements, particularly if he is not acquainted with the local establishments which can provide acceptable distributive education training. He may study the classified section of the telephone directory, consult the Chamber of Commerce and tour the city or consult the advisory committee.

PART V

Advantages and Values of the Cooperative Part-Time Program

To the Student

Acquires knowledge needed for good job performance

Learns as he earns

Learns to work with people and for people

Learns to assume many responsibilities

Gains poise

Develops own cultural values

Develops leadership for tomorrow

To Management or Employer

Obtains trained new workers who have chosen retailing as a career

Increases sales at lower instructional cost

Has an opportunity to work with coordinator in developing the student's work and behavior habits

Offers opportunity in training for future full time employees

Participation in the planning for better instruction of students

To the School

Offers opportunities of projecting the school into the community

Interests business leaders in the school

Helps to prevent drop-outs

Has advantage of advisory committee composed of prominent community leaders.

PART VI

Qualifications of Teacher-Coordinators

Professional preparation in distributive education:

The teacher-coordinator shall be approved under one of the following plans:

Plan I.

The teacher-coordinator shall be a graduate of an approved teacher-training program in distributive education and hold a Class A secondary teacher's certificate.

Plan II.

A one (1) year Class A permit and vocational license may be issued to holders of Class A secondary certificate upon completion of six (6) semester hours or eight (8) quarter hours of credit earned from any of the courses required for a standard coordinator's certificate. He may continue to be approved as a teacher-coordinator each succeeding year upon completion of six (6) semester hours in distributive education as approved by the state supervisor until such time he meets requirements to be certified as a distributive education teacher-coordinator.

A minimum of twenty-seven (27) semester hours or forty (40) quarter hours in specialized education courses shall be reequired for a Class A secondary teacher's certificate for all distributive education teacher-coordinators.

Technical Preparation in Distribution:

Fifteen (15) semester hours in technical courses chosen from the following areas: marketing, accounting, economics, business law, merchandising and management. Ten (10) of the fifteen (15) semester hours will be required from the area of marketing.

Experience in distributive occupations: He shall have had two (2) years of practical experience as a wage earner in business or in a distributive occupation. One (1) year of which shall have been full time employment.

Duties and Functions of a Distributive Education Coordinator

A complete list of duties performed by coordinators would be infinite in length, therefore, this list should only serve as a guide and provide suggestions to the coordinator in performing his duties. The following list of duties is considered essential to the operation of a complete distributive education program in Mississippi:

1. Organization and Promotional Activities.

   a. Make survey of school and community distributive occupational needs.
   b. Counsel with prospective students and with parents of prospective students.
   c. Contact employers and explain the distributive education program.
   d. Recruit, select, and enroll students in D. E. program.
   e. Select and maintain functioning advisory committee.
   f. Make talks before business, civic and school groups to explain the program.
   g. Publicize the accomplishments of the program.
   h. Establish rules and regulations for the operation of the program.

2. Classroom Instruction.

   a. Instruct Distributive Education classes consisting of one or two hours in school each day.
   b. Instruct or supervise students in study of information directly related to their occupation.
   c. Instruct students in information indirectly related to their occupation designed to increase the student's personal development into a more proficient citizen.
   d. Correlate the laboratory experience of students with classroom instruction.
   e. Obtain, prepare, and maintain current and valid instructional aids in accordance with class needs.

3. Coordination-Supervision.

   a. Secure quality placements for students and set up training stations and training agreements.
   b. Plan a schedule of rotated experiences with employers on the Memo of Training Form then agree on a system of supervision.
   c. Arrange students schedule of school and training.
   d. Place students in training stations according to their interest, aptitudes, and abilities.
   e. Carefully follow-up students periodically to carry out Memo of Training Plan and check progress of experience.

f. Use grade sheets to obtain ratings from employers on student progress and ability.
g. Adjust problems of students with employers, school, parents, or others concerned.
h. Visits in homes with parents of students.
i. Works with faculty for general improvement of program.
j. Works closely with businesses of community in satisfying their training needs.

4. Follow-up and Evaluation.

a. Make periodic visits to trainees on the job and to employers.
b. Aid students in making additional adjustments for better progress in chosen occupations.
c. Confer frequently with individual students on personal achievement and training progress, and make recommendations when needed for improvement.
d. Counsel with former trainees to secure information for improvement of program and to follow-up with additional training through the adult program.

5. Related Activities

a. Sponsor local club chapter.
b. Keep records of trainees and work experiences.

6. Establish Relationships

a. Maintain close working relationship with business on employer-employee level.
b. Work to provide better school-community relations by striving to meet distribution training needs in the community.
c. Take an active part in professional activities such as civic groups. parent organizations, faculty meetings, teacher organizations, and merchant organization.
d. Attend extra-curricular activities and functions of the school.
e. Maintain continued publicity designed to educate the public on D. E., it's goals, it's achievements, it's merits, and it's services.

7. Adult Work.

a. Survey community for adult educational needs in distribution.
b. Organize courses.
c. Secure information and instructional materials for adult group needs.
d. Obtain instructors proficient and experienced in areas of courses taught.
e. Release publicity on courses offered.
f. Supervise all D. E. adult courses and instructors.

PART VIII

Organization and Promotion of Adult Evening Classes In Distributive Education

Administration of Adult Evening Classes In Distributive Education

a. Secure an adequate budget for adult classes through the school, making certain that the request is made in sufficient time to permit the school administration to approve it before the beginning of a new fiscal period.

b. Make arrangement for suitable space, either at the high school or some centrally located facility that meets the needs of a particular group or class.

c. Ascertain if an instructor is available to teach the particular class or series of related classes that are to be offered.

d. Promote the enrollment of adults in the class through one or more of the following organizations. (These are not necessarily listed in the order of their particular value, as this may vary somewhat from community to community.

1. Chamber of Commerce
2. Retail Merchants' Association
3. Newspaper, Radio, T. V.
4. Civic Clubs
5. Trade Associations
6. Direct Mail
7. Personal Solicitation
8. Poster Cards in Store Windows
9. Business Management Groups
10. Itinerants (State Department of Education)
11. A Representative Advisory Committee

Suggested Classes That May Be Offered

This is simply a cross section of classes that are approved to be offered in an adult evening program in distributive education. Others may require correspondence with the state supervisor to make certain that it meets the legal requirements for a reimbursable class.

For Management Personnel:	Personnel management, Legal aspects of business, Sales promotion, Record Keeping, Financial Management.
For Supervisory Personnel:	How to train an employee, how to supervise an employee, how to conduct group meetings, how to buy, creative thinking, rapid reading.
Sales Personnel:	Salesmanship, Stockkeeping, Human Relations, Display, Effective Speech, Retail Arithmetic, Credit and Collection.
Specialized Areas:	Interior Decorating, Textiles, Food Service Selling, Service Station Selling, Hardware Product Information, Furniture Sales Training, and many others.

Suggestions in Securing Instructors for Adult Evening Classes

a. Make certain that instructors are qualified in the field in which they are to teach. The local advisory committee should be of value to you in this regard.

b. It is also important, if the instructor is to be a local person that he has sufficient prestige to draw people into the class and to sell his services sufficiently well to have the enrollees want to come back to every class.

c. A lot of good potential instructors need help in putting their knowledge across to students. It is the job of the distributive education coordinator to serve as a teacher-trainer to the instructor.

d. Itinerant instructors are available through the Distributive Education Division of the State Department of Vocational Education. These instructors are available to the local school without cost. Write to the State Supervisor of Distributive Education for the names of these instructors and the classes that they teach.

e. Trade and civic organizations may be used in securing names of potential adult class instructors.

f. Certain trade groups such as the local association of furniture stores, department stores, variety stores, service stations, etc., are sometimes able and willing to bring in outside experts in their particular fields to instruct specialized classes for their specific and related groups.

g. Members of the faculty of your high school and any local college may make excellent instructors in their particular field of study.

h. Promotion of adult evening classes is one of the most important duties of the coordinator who realizes, however, that unless he has a good cooperative program he possibly will not be as successful in organizing adult evening classes. Both should be given their fair share of promotional and supervisory time.

Procedures in Securing Approval for Adult Evening Classes

a. Approval must be secured in advance of the opening of adult evening classes in order to be eligible for reimbursement of the instructor's salary.

b. An Application For Approval In Advance Form must be completed in duplicate, an Outline of the Course to be offered attached to it and signed by the superintendent or someone authorized by him to sign, before it is sent in to the state supervisor of distributive education.

c. When the class is organized an initial report is sent in signed by both the instructor and the coordinator. This report should be sent in as soon as the class becomes stablized in number.

d. A minimum of ten students are required for reimbursable classes. A minimum of fifteen should be enrolled in order to allow for possible drop-outs.

e. Instructors should keep up-to-date and adequate records of attendance for students enrolled in the class.

f. The coordinator should check the classes progression in order to see if it is being conducted in line with the policy for adult evening classes.

g. Coordinators should realize that reimbursement is only on the instructor's salary and cannot be used for any other purpose.

h. Visitations to the classes should be recorded on the Activity Report, as well as number of class members talked with.

Cost of Instruction

a. One of the best public relations aspects of a distributive education program, as far as business people are concerned, is a good adult program for management, sales workers, department heads, supervisors and non-selling personnel.

b. A budget can pay big dividends in engendering goodwill in the community through programs that meet the needs of workers in marketing, distribution and service establishments.

c. At the present time, the State Department of Vocational Education will reimburse two-thirds of the teacher's salary for conducting approved adult classes in distributive education. It may be possible, under certain conditions, to secure 100% reimbursement on certain classes. A small registration fee may be charged for teaching aids and supplies that may be applied to the local costs of the class where no local funds are available.

d. A budget of $1,000.00 should be adequate to pay teacher salaries for twenty-five classes of ten hours each, enrolling probably a minimum of three hundred seventy-five students, with possibly a great many more being enrolled. Note: Four dollars an hour was used as a basis of instructor salary. Note: One-third of above would be local funds.

e. On the basis of the above projections, the value to the community and its' tax payers and voters through the benefits derived through these classes would be most worthwhile both economically and in the general welfare of the trade territory.

<u>Supervision of Adult Evening Classes by Distributive Education Coordinator</u>.

a. It is the local school's responsibility to provide the supervision of adult evening classes. The coordinator of distributive education is trained and qualified to handle this responsibility and should be expected to do so. In larger areas or communities he may require assistance in order to keep him from neglecting his cooperative program on account of a large adult evening program.

b. The coordinator should be aware that the following reports are required on any reimbursable classes:

1. Initial Report; at the beginning of each class
2. Monthly Activity Report
3. Final Report; shortly after the class is completed.

c. All standard report forms are supplied through the state supervisor of distributive education. These may be ordered when supplies become depleated.

d. All approved adult evening classes completed during a semiannual period should be reported for reimbursement.

PART IX

The Local Advisory Committee

a. A local advisory committee is most important and necessary to the successful operation of a good adult evening school program.

b. The coordinator should realize that the advisory committee's function is solely advisory in nature, and involves no administrative responsibilities or authority.

c. Outstanding local business leaders and employees serving on the advisory committee should serve as a most helpful group in keeping the distributive education coordinator and the school informed on local needs and problems which might be alleviated through efforts of the distributive education department in cooperation with local business leaders and organized groups.

d. The advisory committee should be composed of an equal representation of employers and employees. Strong representation from the Chamber of Commerce and the Retail Merchant's Association, should be included in the membership. The coordinator is an ex officio member of the group and should act as secretary.

e. The possible membership should be discussed with the superintendent of schools and preferably a letter be sent out over his signature notifying the individual members of their appointment to the advisory committee. (The coordinator should have previously talked with each individual to ascertain their willingness to serve).

The advisory committee provides a link between the school and community through which their activities can be coordinated. Its use is highly recommended. There must be a constant exchange of information in order to keep the program of distributive education realistic and to satisfy the changing needs of the community.

Purposes and Functions of Advisory Committee:

Advise on course of study.

Planning group for program expansion.

Assists in creating good will.

Help in creating prestige for school, community, and program.

Assist in surveys.

Aid in development of standards.

Help insure a realistic and practical program.

Guide in wage and hour problem.

Assist in promoting adult classes.

Help select adult teacher-coordinator.

Help evaluate all phases of activities.

PART X

Future Leaders in Marketing and Distribution

Distributive Education Clubs of America is a youth activity program which is designed for boys and girls enrolled in part-time cooperative programs in the field of marketing and distribution. It is organized on local, state, and national levels to provide incentives and recognition for D. E. students. It encourages the value of the club as a vital part of the total program.

Aims and purposes of D. E. C. A.

Broadens ecnomic understanding.

Increases knowledge of distribution.

Maintains an inquity attitude toward techniques used in distribution.

Increases abilities in citizenship activities.

Develops an understanding of the social and economic responsibilities of those engaged in distribution.

<u>Importance to the Student</u>

D. E. C. A. provides opportunities for service to the school, community, and nation in the following areas:

Educational activities

Professional activities

Civic activities

Social activities

Benevolent activities

PART XI

Criteria For Evaluation of a Desirable D. E. Program

Organization

1. Is this program in Distributive Education based upon findings of surveys of employment opportunities in marketing and distribution in the area served by the local school?
2. Is an advisory board or planning committee, representing both school and business leaders, used in organizing this program?
3. Is classroom instruction correlated with laboratory training?
4. Do students receive credit toward graduation for both classroom instruction and laboratory training?
5. Do D. E. students spend minimum 15 hours a week with an approved laboratory training agency?
6. Are all state and federal laws adhered to in the operation of this program?
7. Are students enrolled on a basis of need, interest, and ability as a result of proper tests and interviews?
8. Are D. E. students permitted to participate in club activities in the field of distribution?
9. Does this present program meet the career objectives of each student?
10. Is there a detailed training plan contributing to the career objective a matter of record for each student?

Nature of the Curriculum

1. Is the D. E. instruction based on career objectives in marketing and distribution, and basic needs of the community?
2. Does this D. E. Curriculum include the marketing and distribution process?

3. Does this D. E. Curriculum provide for subject areas in addition to the areas of distribution?

4. Is there adequate supervision given to the laboratory training?

5. Is there a definite understanding of the responsibilities in a competitive economic system in the areas of distribution?

Physical Needs

1. Are the following items of equipment available for classroom and laboratory instruction:
   1. Cash register.
   2. Filing cabinet.
   3. Wrapping counter with a variety of supplies.
   4. Wall cases with mirrors.
   5. Models and mannequins.

2. Is there sufficient space provided to meet curricular and enrollment needs?

3. Is the teacher coordinator equipped with a desk and files for counseling with students?

4. Are movable tables and chairs provided to facilitate use of reference materials?

5. Is there convenient storage space provided for materials and equipment not in frequent use?

6. Is the classroom conveniently located near a building entrance?

Cognizant

1. Is the instructional material kept up to date?

2. Does the teacher coordinator maintain sufficient supplementary instructional materials?

3. Are adequate reference materials available?

4. Are self-study materials available for specific instruction?

5. Are there appropriate audio-visual aids available?

6. Does the instructor have a plan of instruction to follow?

Instructional Activities

1. Does the instruction in D. E. contribute to the school's objective?
2. Is instruction directed toward career objectives?
3. Is there evidence of careful planning and preparation for classroom work on the part of the teacher coordinator?
4. Are business resources of the local community used in instruction?
5. Do students assist in planning classroom activities?
6. Are job descriptions prepared for laboratory experiences?
7. Are the laboratory experiences used to develop an understanding of the theory presented in the classroom?
8. Does the instruction include the basic concepts of distribution in addition to specific specialization?
9. Does the teacher coordinator visit in the home of each student?
10. Does the teacher coordinator visit the student's laboratory agency regularly?
11. Is the laboratory training correlated with the student's aptitudes, interests, and abilities?
12. Is a positive approach instilled in the student's attitude of personal responsibility toward the laboratory training?
13. Is there provision for teaching the economics of distribution?
14. Is there provision for teaching management concepts?

Instructional Staff

1. Is each member of the D. E. staff prepared in the subject matter field?
2. Has each member of the staff received training in methods of teaching DE?
3. Has each member of the D. E. staff had wage-earning experience in the field of marketing and distribution?
4. Has each member of the D. E. staff had sufficient preparation in related areas in the field of distribution?

5. Has each member of the D. E. staff developed good relations with the business community?

6. Has each member of the D. E. staff maintained an interest in the activities of the business organizations in the local community?

7. Has each member of the D. E. staff maintained an active interest in the professional organizations?

8. Has each member of the D. E. staff maintained active participation in in-service education through formal and other professional activities?

9. Does each member of the D. E. staff maintain proper lines of communication?

Methods of Evaluation

1. Are the evaluation activities an integral part of the classroom instruction?

2. Is individual progress recorded and used for guidance and instructional purposes?

3. Is the laboratory experience training used as a basis of student education as well as the classroom proficiency?

4. Is the student's evaluation of laboratory training made jointly by the employer and teacher coordinator?

5. Is the student's evaluation made in terms of needs of the laboratory experience of the student as well as in terms of career objectives?

6. Is there sufficient follow-up surveys conducted to evaluate the student's educational outcomes?

Achievements

1. Do students show sufficient signs of improvement in skills and attitudes necessary for the distributive occupations?
2. Do the students show sufficient knowledge and understanding necessary for success in the distributive occupations?
3. To what extent are students developing moral and ethical standards related to distributive occupations?
4. Are students being informed about the varied opportunities in the field of distribution?

Form DE-1

PROPOSED BUDGET AND APPLICATION FOR AID IN DISTRIBUTIVE EDUCATION CLASSES

For the Fiscal Year Beginning July 1, 19____, and ending June 30, 19____.

(Due in State Office on or before June 15—Submit 3 copies)

From:.....School Board, Post Office.....

To: Mississippi State Vocational Board
Box 771
Jackson, Mississippi

County of.....

Handbook for New Vocational Teachers.

Nevada Univ., Reno. Max C. Fleischmann Coll. of Agriculture.
MF AVAILABLE IN VT-ERIC SET.
PUB DATE - ND 81p.

DESCRIPTORS - *VOCATIONAL EDUCATION; *VOCATIONAL EDUCATION TEACHERS; *INSERVICE TEACHER EDUCATION; *TEACHER ROLE; *MANUALS; TEACHER EDUCATION; TEACHER ORIENTATION; BEGINNING TEACHERS; STUDENT TEACHERS

ABSTRACT - This handbook has been prepared for the vocational education major, student teacher, new teacher, and the adult teacher with limited teaching experience. Designed to highlight the simple but necessary tasks of successful teaching, one page is used for each main idea, supplemented by line drawings. Chapters include: (1) Characteristics of Successful Teachers, (2) Local Policies and Regulations, (3) Planning the Instructional Program, (4) Writing Lesson Plans, (5) Preparation for the Class, (6) How to Teach the Class, and (7) Evaluation and Testing. ACKNOWLEDGEMENTS

Much valuable assistance was received from Dr. Harlan E. Ridenour, Director of Ohio Vocational Agriculture Material Service, Ohio State University.

Credit is also given to the teacher-educators and state staff in Ohio for their excellent ideas for Trade Extension teachers.

Assistance also was given by Professor T. A. Butler, Dr. L. P. Herndon, Agricultural Education and Mechanics Department, University of Nevada. Mr. J. R. Peddicord, State Supervisor of Agricultural Education and Harvey G. Thiel, Trades and Industrial Education Supervisor, State Department of Education, Carson City, Nevada.

PREFACE

This book has been prepared for the Vocational Education major, student teacher, new teacher and the adult teacher with limited teaching experience. The purpose is to show the beginner the role of the teacher and illustrate the simple but necessary things that should be done to make his teaching a success. This is also meant to be used by the veteran instructor as a reminder of the basic fundamentals of teaching.

It is believed that most of the failures and poor teaching result from lack of doing the things listed in this small book.

It is also believed that most discipline problems, bad school and public relations problems can be prevented by mastering the fundamentals listed.

It is conceded by the authors that many practices and methods used by successful teachers are not included in the text, but those that are listed are essential to the vocational teachers' success.

The handbook is designed to hit only the highlights. For this reason one page is used for each main idea.

It is hoped that all new teachers will seek more complete references for greater detail on ideas suggested in this manual.

The Authors

627

CHAPTER I

CHARACTERISTICS OF SUCCESSFUL TEACHERS

INTRODUCTION

The art of successful teaching can be mastered by practically all normal, well trained individuals who strive to develop the characteristics described in this section.

Teaching is not a "fixed" skill but one where the teacher "practices" his profession. Classes and individual students vary from year to year. They have different needs; also our society and "world of work" is not static but constantly changing. For these reasons the teacher must constantly adapt and improve to best meet the changing times.

The assumption is that successful teachers in general act in a similar manner; but have developed their own peculiar personality and style to best use their own God-given talents.

By making the best use of one's own distinctive personality, tempered by experience, study and hard work, can a teacher effectively bring all factors that are needed in focus and achieve success in teaching.

A successful teacher **is** or has these attributes: P. 3–7

1. Strives for success.
2. Scholar.
3. Professional worker.
4. Part of the educational team.
5. Optimistic for the future.

A successful teacher *does* the following: P. 8–14.

1. Strives to develop the maximum potential of his students.
2. Plans a well organized educational program.
3. Functions as a good vocational educator.
4. Provides management and organization for the program.
5. Takes command.
6. Seeks new educational media.
7. Promotes his program.

Teaching success results from a combination of what the teacher *is* and what he *does*. Each is equally important for teaching success. It is important to note they are not identical. In the observation of successful teachers, it is usually more difficult to see and explain what a teacher does than it is to identify teacher attributes. Learn the earmarks of quality teaching.

THE SUCCESSFUL TEACHER STRIVES FOR SUCCESS

The goal of the new teacher should be to assume the characteristics of the successful teacher.

Becoming a successful teacher requires a long period of hard work and experience. Students are not perfect and have great differences and great needs. The rewards that come to the teacher are few and hard to define. A successful teacher believes that the primary hope for the future lies in education.

He is an alert, aggressive, dynamic individual who will spend the time needed to make his program a success.

He is creative, imaginative, optimistic and is opportunistic in making the most with what he has to work.

630

THE SUCCESSFUL TEACHER IS A SCHOLAR!

Each teacher is in the lifelong business of self improvement!

1. Has a satisfactory scholastic record.
2. Reads worthwhile publications in the vocational, business and education fields.
3. Is a keen observer of his students, successful operators and employers.
4. Knows how to relate technical knowledge to actual problems of students.
5. Participates in workshops, seminars and professional and technical areas of knowledge.

Outcome or results

His students, through their work and accomplishments, exemplify good scholarship.

068631

THE SUCCESSFUL TEACHER IS A PROFESSIONAL WORKER

1. Organizes and manages his own program under the supervision of others.

2. Supports and promotes his profession and is loyal to his colleagues.

3. His appearance, actions and manner are geared to meet the best interests of the profession.

4. Answers correspondence, completes reports and becomes a part of the total educational team, local and state.

ECG 632

THE SUCCESSFUL TEACHER IS A PART OF THE EDUCATIONAL TEAM!

1. Promotes the entire school program.
2. Cooperates with school administration.
3. Carries his fair share of the "extra duties" associated with teaching.
4. Works with parents.
5. Cooperates with state supervisors, teacher educators and others in the development of the total program.
6. Joins and takes an active part in professional educational organizations – local, state, national.

633

THE SUCCESSFUL TEACHER IS OPTIMISTIC FOR THE FUTURE.

1. Believes in the future.

2. Believes in the worth of people and has faith in the youth and adults of his community.

3. Sees the good side of things.

4. Is able to pass his enthusiasm on to others.

5. Believes in the worth of vocational education and has faith in his program.

THE SUCCESSFUL TEACHER STRIVES TO DEVELOP THE MAXIMUM POTENTIAL OF HIS STUDENTS.

He works with guidance counselors and others to understand his students.

1. Tries to determine vocational and scholastic goals of his students.

2. Tries to develop in his students a love for learning and their creative talents.

3. Assists students to discover knowledge as well as the world of work and to finally become a well adjusted citizen.

PCA 635

THE SUCCESSFUL TEACHER PLANS A WELL ORGANIZED EDUCATIONAL PROGRAM.

1. Plans a curriculum for his department based on the vocational objective of his students.

2. Uses an advisory council, successful individuals, and his observations of the "world of work" in planning his instructional program.

3. Plans a meaningful educational program for his students.

4. Plans for supervised work experience programs for his students.

5. Develops educational objectives that may be observed and measured.

6. Plans to evaluate his educational program in terms of his educational objectives.

636

THE SUCCESSFUL TEACHER FUNCTIONS
AS A GOOD VOCATIONAL EDUCATOR.

1. His lessons have utility.

2. His instructional program is aimed to develop vocational competence in his students.

3. Assists students to find employment and become successful workers.

4. Knows the needs of parents, employers and the self-employed in his service area.

5. Relates classroom teaching to occupational work experience programs.

6. Supports the principles of vocational education.

Outcome or results:

The value of his program can be measured by the occupational success of his students.

THE SUCCESSFUL TEACHER PROVIDES
THE MANAGEMENT AND ORGANIZATION FOR THE PROGRAM.

1. Determines the most effective use of his own time.

2. Wholesales his own time by determining job priorities, group activities and various methods of teaching that will bring the greatest results according to effort expended.

3. Develops and uses student leaders. He authorizes, deputizes and supervises students and others.

4. Plans varied and adequate work that provides meaningful learning experiences for all.

5. Organizes his teaching materials, the facilities and classroom for best results.

THE SUCCESSFUL TEACHER TAKES COMMAND.

1. Has a high concept of his own worth.
2. Provides leadership.
3. Determines educational objectives.
4. Determines learning activities of his students – assignments, practice, projects, reports, etc.
5. Sets standards.
6. Gives directions.
7. Evaluates progress and determines grades.

THE SUCCESSFUL TEACHER CONTINUALLY SEEKS NEW EDUCATIONAL MEDIA FOR USE IN TEACHING.

1. Has the nose of a bird dog to find new ideas, innovations, resource materials, and educational media.

2. Makes his instruction interesting, dynamic and vital.

3. Collects actual objects to enrich lessons.

4. Is constantly improving his library.

5. His curricula planning includes plans for educational media to be used in teaching.

THE SUCCESSFUL TEACHER PROMOTES HIS PROGRAM.

"My program gets results!
I want to tell you about it."

1. Never misses an opportunity to inform school administrators of the results of his program.

2. Informs his students of the accomplishments of his department.

3. Works with lay individuals, successful operators and community leaders.

4. Has an organized public information program. Uses mass media.

5. Shows appreciation for those who assist and support program.

S641

CHAPTER II

LOCAL POLICIES AND REGULATIONS

INTRODUCTION

"Sir, before starting, I have a few questions."

The new teacher should be knowledgeable on all points listed in this section before starting to teach. After employment he should be constantly aware of policy changes.

Many failures and difficulties have arisen because the new teacher did not become informed on the important points in this chapter. He must take the initiative to make himself informed.

The problem for the new teacher is *where* and *how* to get the information.

Suggestions:

1. Ask the prospective employer about these basic points before signing a contract.

   The student teacher should ask questions on these points before or as soon after he starts his student teaching as possible.

2. After employment have frequent talks with the school administrators.

3. Ask questions from teachers in the department.

4. Review school policy manuals.

5. Make careful observations.

6. Learn sources of funds and procedures of finances.

Request information from the State Supervisor on availability and use of vocational funds.

GENERAL SCHOOL REGULATIONS AND POLICIES
AND
INFORMATION NEEDED BY THE NEW TEACHER.

Don't be in the dark about these!

CHAPTER III

PLANNING THE INSTRUCTIONAL PROGRAM

INTRODUCTION

Teaching success depends upon the efficiency and skill demonstrated by the teacher in performing the five functions listed below.

1. The quality of the instructional plans made in advance of the class. Chapter III.
2. Concise and meaningful written lesson plans. Chapter IV.
3. The extent immediate preparation is made to insure readiness for the class. Chapter V.
4. The skill and efficiency displayed in teaching. Chapter VI.
5. Evaluation of the instructional program. Chapter VII.

In planning the instructional program for vocational technical type programs, the teacher is concerned with providing training that makes the student employable. He functions as a vocational educator described on p. 10 in order to obtain a high degree of employability and other outcomes described on p. 26. The teacher must *plan, organize, manage* and *administer* the program to see that it adjusts and keeps in step with the advancements as they are made in the occupation. If this is accomplished, the following essentials are necessary.

1. The program is directly related to employment opportunities, determined by cooperation with occupationally concerned and competent individuals and groups.
2. Courses are up-dated on the basis of advancements in the occupation.
3. Facilities and equipment used in instruction are comparable to those found in the particular occupation.

4. Adequate instruction *time* is provided to accomplish the objectives.

5. Vocational guidance is effective to *enroll* and *place* those students who can profit from the instruction.

6. Provision is made for supervised occupational experience programs.

7. The teachers are competent in occupational and teaching skills. The teacher studies and observes methods used by successful employers and workers in the world of work. He also improves himself by added professional training.

In planning the instructional program, the teacher must be aware of the factors which influence the quality of the instructional program. The final outcomes and results measured in terms of student accomplishment are largely determined by three factors:

1. The quality and quantity of the students themselves.

2. The quality of the total educational program provided by the school. This includes school support, as well as factors listed on p. 17.

3. The quality of the teacher. What he *is* and what he *does*. pp. 3-14.

The above points are discussed more completely in Chapter VII, Evaluation and Testing.

Page 24 represents an overview of the total plans for a department. Program plans include all of the course plans for the department. Course plans include all of the unit or major jobs in sequence. Unit or major job plans include lesson or operation plans. Objectives and evaluation are needed for each of the above divisions of the instructional program.

649

PLANNING IS A DECISION MAKING PROCESS.

The teacher uses all available help from outside sources to develop his instructional program, but in the final analysis the decision is his.

The instructional program must be planned well in advance of the class so a "good" start can be made. Adjustments can be made as the course proceeds.

Definitions

Unit or job: The subdivision of a course.

Lesson or operation: The subdivision of a unit or job.

Examples:

Course: Welding
Unit or job: Acetylene welding
Lesson or operation: Weld two pieces of metal in flat position

Course: Animal science
Unit or job: Sheep production
Lesson or operation: Fattening show lambs

PLANNING THE TOTAL INSTRUCTIONAL PROGRAM

Know what you are going to do and how you are going to do it.

1. Program plans – includes plans for all of the courses or years that a typical student is in the department.

2. Course plans – units in proper sequence – for a year or semester.

3. Unit plans – special subject matter areas – typically 4 to 8 weeks.

4. Lesson plans for each session – typically from 1 to 3 days. All plans should be written on a standard form. Organize for class room use – 3 ring binder or book.

DECISIONS ARE YOURS
IN PLANNING THE INSTRUCTIONAL PROGRAM.

1. What long time results should I expect from my teaching? P. 26.
2. What are the needs of my students? P. 27.
3. What is my teaching situation? P. 28.
4. What subject matter can be taught as part of the adult program, on the job, and by the other departments in the school. P. 29.
5. What are my objectives? P. 30–32.
6. What shall I have my students do? P. 33.
7. What books, bulletins, charts or films shall I use? P. 34–36.
8. Which teaching method will get me the greatest results? P. 37–41.

WHAT LONG TIME RESULTS SHOULD I EXPECT FROM MY TEACHING?

1. A high percentage of students are:
   a. effective leaders in related organizations;
   b. gainfully employed;
   c. effective workers in industry, agriculture and business.

2. The results of the instructional program should be reflected in improvement in economic efficiency, productivity, organization and management of the farms, firms and industries within the service area of the schools.

3. Students are assisted to meet educational and employment goals and assume their roles in society.

WHAT ARE THE NEEDS OF MY STUDENTS?

1. Home background – social and economic.
2. Interests, likes, dislikes.
3. Initiative.
4. Potential.

HOW DETERMINED?

Home visits.

Standard tests.

Individual conferences.

Observation on the job.

Class record.

Guidance counselors.

WHAT IS MY TEACHING SITUATION?

The teaching situation is the quality and quantity of *what is there* which has a direct bearing on teaching.

1. School – financial support, organization p. 17.
2. Students – abilities, background – The new teacher must determine where the students are in the instructional program before he can make teaching plans.
3. Time available for instruction.
4. Teaching resources – facilities, references p. 18.
5. Resources of the school service area.
6. Distances – businesses – availability of supplies, etc.
7. Other programs – adult, out of school youth and types of other classes within the school.

Can the instruction be taught in a real situation in the natural surroundings, using methods, tools, etc., as found in the occupation?

WHAT SUBJECT MATTER CAN BE TAUGHT AS PART OF THE ADULT PROGRAM, ON THE JOB, AND BY OTHER DEPARTMENTS IN THE SCHOOL?

"I can't run the whole show."

Some jobs are too complicated or time consuming to fit into the high school program. These should be delayed for post high school or adult programs.

The teacher's problem is to determine what he can adequately teach with the time and resources available. Direct duplication in teaching subject matter should be avoided in the high school as far as the same students are concerned.

WHAT ARE MY TEACHING OBJECTIVES?

Objectives are the means of providing direction! They provide the basis for –

Goal setting – What skill? What approved practice? What knowledge or ability should students acquire?

Evaluation – To what degree did my lesson hit the target?

In writing objectives think in terms of the specific changes that result in the student by having studied the lesson. He should be a changed person by having learned this particular lesson.

Objectives assist the teacher to limit, to be specific, to determine importance and what is essential.

IN DETERMINING OBJECTIVES, FOCUS ON

STUDENT LEARNING EXPERIENCE

NOT ON

TEACHER ACTIVITY

STEPS TO TAKE IN WRITING OBJECTIVES

1. **Name the terminal behavior.**
   Develop the ability to measure machine efficiency.

2. **Describe the conditions under which the learning will be taking place.**
   Determine engine operating efficiency under normal operating conditions.

3. **Describe how well the learner must perform.**
   Make final adjustments under actual working conditions.

WORD OBJECTIVES SO THAT THEY MAY BE OBSERVED AND MEASURED.

Words open to fewer interpretations	Words open to many interpretations
To write	To know
To recite	To understand
To identify	To really understand
To differentiate	To appreciate
To solve	To fully appreciate
To construct	To grasp the significance of
To list	To enjoy
To compare	To believe
To contrast	To have faith in.
To demonstrate	
To apply	
To rank	
To do.	

The left hand column above is *preferred* because the outcomes can be observed and measured.

WHAT SHALL I HAVE THE STUDENTS DO?

The teacher must determine specific operations or lessons in order of difficulty. The student must learn the objective for the total job or unit. Each operation should be evaluated. The student must successfully do each operation before going on to the next. As soon as the student completes the required operations or lessons he should go on to practical jobs that apply the information learned.

Example: Unit in arc welding.

Operation	Joe x	Rex x
Equipment set up	1	2
Run straight beads	2	2
Flat butt weld	1	4
Flat edge and lap weld	3	2
T weld flat and vertical	2	5
T weld – overhead	4	3
Extra activities		

x Student grades on each operation.

WHAT BOOK, BULLETIN, CHART OR FILM SHALL I USE?

1. What is available? How many?
2. What can I order?
3. What can I prepare myself?
4. Which contains the subject matter content I wish to teach?
5. Is it timely, up-to-date and is the content of critical significance?
6. Can I use it within time and conditions for use?
7. Will it make best use of my time and the student's time?
8. Does it help in student practice or assignments?
9. Which can *I* use most effectively?

ROLE OF EDUCATIONAL MEDIA IN THE TEACHING LEARNING PROCESS

"I use them because they help!"

1. Stimulate interest.
2. Provide concrete basis for development of understanding.
3. Supply basis for developmental learning.
4. Offer a reality of experience which stimulates the learner.
5. Motivate student to investigate and discover.
6. Increase retention.
7. Teach the poor readers and keep them involved in the class.
8. Keep the attention of the class focused on the things the teacher wants the students to learn.

Educational media are excellent means for imparting information, and are especially useful where a complex mechanism is to be explained, to show relationships, or to present a sequence of procedure.

How does your educational media rate? P. 36.

FACTORS THAT INFLUENCE THE SELECTION OF EDUCATIONAL MEDIA

	Must apply to lesson	Time allotment	Student participation	Attention demanding	Technical accuracy	Easily constructed	Flexibility	Versatile	Economic	Availability	Simple in design
Motion pictures											
Slides or film strips											
Opaque projections											
Transparencies											
Pictures, flip charts											
Blackboard											
Printed materials											
Models or mock up											
Actual objects											
Recordings											
Field trips											

In the selection of a **certain** educational media there are many factors that influence your choice. Across the top of this chart are some of the most common factors.

WHICH TEACHING METHOD WILL GIVE ME THE BEST RESULTS?

"The method I use depends upon...:"

Good teachers use a variety of methods. In all methods the teacher is still in charge and provides leadership. His role varies with the method used.

Student involvement is an important factor in selecting all methods.

073664

THE SELECTION OF A METHOD DEPENDS UPON THE LESSON OBJECTIVE AND THE TEACHING SITUATION.

The instructional program should include teaching the class as a whole, part of the class, individual instruction. Certain methods are best for each. The subject matter to be taught is a primary factor to consider in selecting a method.

Methods can be classified according to who is the center of activity.

Teacher centered

Lecture
Illustrated lecture
Demonstration

Group centered

Panel
Symposium
Debate
Conference
Brain storming

Student centered

Supervised study
Student reports
Laboratory
Study guide
Programmed instruction

Object centered

Field trips
Displays
Motion films
or machine

Usually in a given lesson one method is predominately used; however, good results may be obtained by using several methods. Different teachers will effectively use the same general method in different ways.

03865

LECTURE METHOD

Use: In situations where the subject is complex and there is a limited amount of time, also where the instructor has superior knowledge.

Introduce new material or give instructions.

To be used sparingly. Transfer problems from instructor to student as quickly as possible. Students are passive.

ILLUSTRATED LECTURE METHOD

Use: It provides insight or depth into a problem. Teacher shows as well as explains subject matter.

One of the most effective methods when used with slide set, flip charts, actual objects, etc.

Teacher involves students, reviews, questions and tests as lesson proceeds.

Students are usually passive.

DEMONSTRATION METHOD

Use: To teach manipulative type jobs where the end product is for the student to be able to build or make an object or perform an operative function in a specific manner. The objective is to show *how* and the correct *sequence* in which the job is done.

Procedure:

Prepare: (teacher)
- motivation for the student to receive instruction and
- reasons for the job and importance.

Present: (teacher)
- carefully and completely
- give steps and key points or information with each step.

Try out: (students)
- have students do work under supervision
- correct mistakes.

Testing or follow up:
- put him on his own
- return to normal supervision.

PANEL OR GROUP CENTERED METHOD

Advantage: Burden is on the group rather than the teacher. Provides various opinions.

Use: Students have had prior study or have special knowledge.

Types of lessons:

1. To solve a particular problem.
   Example: How can we improve our chapter?

2. Role playing.
   Example: Selling of an object or business.

3. Use of a particular thing.
   Example: The use of a cooperative selling or buying organization.

Teacher role: At start introduce topic and set ground rules, and define audience participation. When needed may act as a stimulator, questioner, interpreter. At end with class make summary.

SUPERVISED STUDY METHOD

Use: Gain information to solve a problem, background, or special reports and projects. Students study under teacher supervision.

PROCEDURES

Determine educational objectives.

Develop a good set of study questions.

Provide each student with adequate references and note book.

After study period, discuss questions and develop a summary or list of approved practices.

Prepare a short written test, based on objectives, on the material studied.

PROBLEM SOLVING METHOD

Use: Managerial or decision making lessons.

PROCEDURE

Outline the situation.

Identify the problem.

Determine the factors bearing on the problem.

Determine the pertinent information
from student experience,
through student study assignments,
through observation,
through teacher presentation.

Assist students in seeing the relationship of one list of information to another.

Assist students in generalizing and forming conclusions.

Form and try trial solutions.

Select most appropriate solution and apply to life situation.

FIELD STUDIES

Types

1. Outstanding farms or ranches.
2. Superior businesses.
3. Specific type jobs.

Cautions

1. Determine specific aims.
2. Select industry or job that best fits.
3. Prepare students for trip. Suggest questions for students to ask.
4. Make student assignments for trip.
5. Require report after trip.

It is necessary to plan carefully each step of a field trip. The success or failure of a field trip is in direct ratio to the amount and caliber of this groundwork.

Teacher role at the location

Introduce owner.
May act as a group leader.
Ask questions, if needed, to bring out important points.
Thank owner at end.

CHAPTER IV

WRITING LESSON PLANS

INTRODUCTION

Meaningful written lesson plans, made in advance of the class, are the best insurance a new teacher has against failure. As a teacher matures in the profession, his thought processes in lesson planning become somewhat automatic, if he constantly evaluates and improves his plans with use. By repetition he soon learns to select rapidly his objectives, teaching method, motivation, student application and evaluation. Lesson planning is mentally teaching the class beforehand.

Writing lesson plans is not easy for the inexperienced teacher. A teacher must organize his schedule to allow time for lesson planning. A new teacher should not expect perfection on the first try. The teacher, for success, must observe the following points:

1. *Lesson plans must be written.* Thinking through how the lesson is to be taught is necessary, but this is not enough. The writing of the lesson plan forces the teacher to be specific and answer the questions on p. 48.

2. Lesson planning should be done in rather large units and all planning should be developed to fit into the total plan p. 24. In writing any given lesson plan, a teacher must be fully aware of both the lessons to be taught *before* and *after* it is to be used.

3. The plan should be written in a manner so that the teacher can use it teaching the class, and also be used by the substitute teacher.

4. The plan should be realistic. Only include *what* and *how* you actually plan to teach.

5. The educational media to be used in teaching the lesson should be listed in the lesson plan. Lesson planning should be done prior to ordering educational media. The best teaching can be done where the lesson plans, filing systems, and "hardware" for showing educational media are all well organized and coordinated.

6. The lesson plan should include how the new knowledge is going to be used on the job, as well as the testing and evaluation of student learning.

7. Lesson plans must be *revised* with use.

8. There must be an orderly method of *storing* and *using* them. A large 3-ring binder is recommended for each course. Lesson plans should be numbered and arranged in the proper sequence in the units that make up the course.

9. All lesson planning should not originate with the teacher. Usually he can adapt the work of others to his own particular situation. He should always be looking for improved ways of doing things p. 13.

FORMS FOR WRITING LESSON PLANS

There are many types and forms of lesson plans but most lesson plans include the following:

1. Name of the unit or enterprise.

2. Name, number, and amount of time for the lesson.

3. Situation. May not be written but is considered in the formulation of the objectives.

4. Objectives.

5. Method or procedure.

6. References and materials to be used.

7. Introduction or motivation – why or reasons for lesson.

8. Presentation – basic information, steps, procedures, etc.

9. Application – period of tryout, correction of procedures.

10. Testing and follow-up work on an actual job, summary, use of knowledge.

674

THE WRITTEN LESSON PLAN IS THE ROAD MAP FOR THE CLASS

"Good teaching is a matter of moving from step to step."

There are three important questions in lesson planning.

1. What do *I need to do?* (teacher)
2. What do the *students need to do to learn?*
3. What should be done to meet my goals with my means in this particular situation?

The plan answers the following questions:

1. *What* I plan to do.
2. *How* I plan to do it.
3. Does it list the *teaching resources or materials* to be used?
4. Will techniques listed motivate students?
5. Is the presentation *dynamic, vivid* and *vital?*
6. Will the student learning activities get the desired results?
7. Is the material taught measurable and useful on the job?

875

TYPES OF LESSONS

In writing lesson plans, it is important to keep in mind the outcomes or results expected. These can, in most cases, be classified into three distinct types as follows:

(a) Managerial or decision making.
(b) Manipulative – the mastery of a specific skill(s).
(c) Informational – new knowledge, appreciation and understanding.

In practically all lessons, a part of each of the above are included. In spite of this, however, the major outcomes are distinctive enough that lessons can be classified according to one of the three major types.

The lesson plan for each type follows the same general format. Note in this chapter the discussion and examples for managerial, manipulative, and informational lesson plans. If a new teacher can use and prepare lesson plans for these three general type lessons, he should not have difficulty with writing any lesson plan and should become more effective in his teaching.

MANAGERIAL OR DECISION MAKING LESSONS

These are mainly mental. They require a knowledge of factors important to the decision. They are concerned with what, when, where, costs, amounts to use, alternatives or choices.

Managerial type jobs are most important in teaching vocational education. They should make a substantial part of the course because they are a means to teaching students to think.

"The first fruits of all true education is the ability to think."

The success of any business is dependent upon making the correct decisions. For this reason the teacher should strive to help a student analyze jobs so he will ask the right questions to get the facts, evaluate the validity of informational sources and plan a course of action to meet the problems in his situation.

Methods used in teaching managerial type lessons.

Problem solving.	Supervised study.
Debate and/or interviews.	Field trips.
Conference.	

MANAGERIAL LESSON IN PROGRESS

Teacher with help of students develop important factors and information needed in making a decision or developing a plan for action.

Practically all managerial type lessons fall into either of the two categories.

1. Should I buy new, replace, repair, remodel, construct, rent, lease, etc.

2. What type business or effort shall I go into – potential income, expense, volume, overhead costs? What are the hidden or added expenses, such as taxes?

The objective of managerial type lessons is for the student to make the correct decision or know the factors to consider in making the decision. They can be evaluated by the quality of decisions made by the student; also by the degree of insight displayed by the student in arriving at the decision and the inclusion and weight given to all important factors. These can best be evaluated on the farm or job as part of the directed work experience program.

Managerial Type Lesson (example)

Lesson: What kind of machine shall Joe buy?

Step I – Preparation or introduction
Give examples of how large amounts of money are lost due to lack of care in the selection of machines.

Step II – Presentation

Factors	Information Needed
1. Use	1. How much and what kind of work will be done?
2. Kinds and types available	2. What kinds and types of machines are commonly used in the area?
3. Service	3. Services provided by the distributor?
4. Cost	4. What is the cost of several types of machines?
5. Other factors	5. What other factors are important?
6. Suggested plan for action.	6. List justification for decision.

Step III – Application or try out
Students in supervised study find answers to questions listed in information needed.

Step IV – Testing or follow-up
Short written test on lesson.
Assist student to implement the plan.

MANIPULATIVE TYPE LESSONS

Manipulative type jobs include the broad area of skills or performance of tasks with the hands. The end result is for the student to be able **to do** an operation and proceed in definite steps. Examples: to type, to weld, to operate a machine, etc.

Steps in writing lesson. Determine the following:

1. Teaching situation.
2. Objective or skill to be learned.
3. Equipment and materials needed.
4. List the steps in the order in which the operation is done. For each step list the critical information or key points which if not done or known will cause the job to fail.

The evaluation is best done by a performance test. Can the student do the job as demonstrated and get the expected results? If he cannot, either the teacher gave a faulty demonstration or the student failed to learn.

679

Manipulative Lesson Plan (example)

Operation: Start a car.

Situation: Car has automatic transmission.

If car had a standard shift the plan would be changed. Students have had no experience, but want to learn.

Step I – Preparation and Introduction

Explain briefly how car runs and why correct starting procedures are important.

Step II – Presentation – Operation Breakdown

Steps	Key Points
1. Place shift in park.	1. Safety – Read symbols P.R.D.
2. Turn on key.	2. Types starting systems.
3. Depress gas feed.	3. Slight – avoid racing engine.
4. Start engine.	4. Check – gauges working.

Step III – Application or try out

Students explain each step and why as they start car.

Step IV – Checking and Testing.

INFORMATIONAL LESSONS

Informational type lessons are for greater appreciation, understanding and background. They have a limited place in vocational education unless tied to a management type job. A small percentage of lessons in Vocational Education should be of this type.

Method:

Lecture or illustrated lecture.
Study questions.
Motion films.

Examples of informational type lessons.

1. Types of materials and use.
2. History of the FFA or related organizations.
3. Keeping up-to-date with advanced information.

The success of the lesson is evaluated by the degree to which the student knows the basic information. It is usually evaluated by a written test.

Information Type Lesson (example)

Lesson: History of the FFA

Motivation: Teacher shows film on national organization. After this he explains the organization and how it functions.

Supervised Study Period: Students have official manuals and resource material. The student writes the answers to the questions in his note book.

1. *Rank* the purposes of the FFA in the order you think are most important.

2. *List* three awards that you may earn in the FFA.

3. *Describe* in your own words conditions at the time the FFA started.

4. *Draw* the FFA emblem and label the purpose of each symbol on your drawing.

5. *How do* the state and national officers assist the local chapters?

Class Discussion: Each question is discussed by the class.

Evaluation: Written test.

Note: Each question requires that the student apply or interpret information read rather than merely copying from the book.

CHAPTER V

PREPARATION FOR THE CLASS

COUNT DOWN! There is no substitute for a good start!

"She'll go if all is ready."

Minutes of preparation before the students arrive prevents frustration.

Have materials ready before class starts.

All visual materials, tools, equipment, actual objects, blackboard, chart stand, film projector should be ready for use.

Check in advance to see that they function. Practice before class on unfamiliar jobs.

START CLASS ON TIME

The class should always be started on time. Get the students in the habit of being on time. Have a definite starting time and stick to it. Expect them to be on time and they will be.

CHECK PHYSICAL FACILITIES

This is particularly important with adult classes. Adults are more aware of heating, lighting and their physical surroundings than younger students. They usually come to class after a hard day's work. Make the room as comfortable as possible.

Watch students for signs of sleepiness – open windows, turn down heat, etc.

CHAPTER VI

HOW TO TEACH THE CLASS

INTRODUCTION

If a teacher has done a careful and complete job of planning, and has made the immediate preparation for the class, the actual teaching should be easy. All of the ideas previously given in this book are worthless if the teacher doesn't follow through in the actual teaching process.

The teacher must keep these questions in mind – What is the maturity, ability and background of the student as it relates to the lesson I am teaching? Have I discovered what the student knows and then teach accordingly? Am I proceeding in a dynamic and interesting manner? Am I flexible enough to adjust to vital teaching situations that may arise, yet follow a teaching plan?

When the teacher signs his contract, he declares himself to be for beneficial learning and against sloppiness, indifference and unemployment. The stakes are high, dear teacher, read on!

A great teacher once said, "Good teaching requires three things. First a teacher who knows his *subject matter*. Second, he knows *how* to teach. Third, he is a *Ham*."

Usually the inexperienced teacher will spend a disproportionate amount of his time in trying to master the subject matter. Knowledge of subject matter is important, but preparation does not stop with it. He must also plan how to teach and follow the suggestions in this chapter on teaching. The teacher should not forget his role as an actor. He tries to hold attention and create interest.

Learning is an active process. We learn by doing. This means we learn to think by thinking. We learn to do a manipulative type operation by actually performing the process. We learn to make decisions by making decisions. We learn to be creative by being creative. Often well meaning teachers make their classes sterile by too much structuring including determining *what* and *how* things are to be done. Thus they limit discovery and stifle initiative.

In the same terms *teaching is an active process.* It requires action on the teacher's part to get the learning process within the student in motion. This is not done haphazardly, but requires concerted effort on the teacher's part in order for the *teacher-learning* process to be most effective.

The teacher should recognize there is a certain amount of annoyance in learning. Most students are mentally lazy. There appears to be a resistance to learning in most students. The teacher in a class is competing for the student's attention. His teaching must literally "tune out," for example, thoughts of love, home and job in the student's mind. This requires positive, deliberate action. As we move into individualized instruction by the use of varied means such as programmed instruction, uni-packs, machines, etc., it will require greater effort and ingenuity to offset student indifference and mental laziness. Students respond to guidance, direction and leadership.

The role of the teacher in teaching classes generally proceeds in the order listed below:

1. Motivate and engage the student in the learning process.
2. Vividly present the concepts and principles to be learned. Use educational media when beneficial.
3. Involve the students by asking challenging, meaningful questions. Force them to think and participate. Learn to use *silence* as a technique.
4. Direct learning by supervising student practice or application. Correct mistakes and wrong conceptions as they arise. Solve student learning problems.
5. Involve students in activities that will challenge their imagination, initiative and creativity. Make the student an active partner in determining what *he will do to* learn.
6. Evaluate learning and progress. Diagnose student learning problems and prescribe appropriate learning experiences.
7. Develop ways and means for assisting the student to use the knowledge learned at school, on the job or in daily life.

883 687

8. Up date the course content and evaluate course materials. Select and use course content that is pertinent to the world of work.

It is impossible to cover all of the facets and innovations and concepts in teaching in this small book. It is important that the new teacher study these and become familiar with them. The authors have tried to include only the basic fundamentals of teaching. It is important that the new teacher first get a good grasp on techniques and fundamentals included in this book. After that he can handle practically any teaching situation that develops. Due to the limited space only the J.I.T. (Job Instructional Training) method will be discussed. It consists of four steps on how to teach pp. 67-70. This is as efficient a pattern of teaching vocational classes as has been devised.

THE TEACHER SHOULD MAKE USE OF STUDENT INTERESTS AND NEEDS

If the teacher knows his situation and plans his program accordingly, teaching becomes not only easier but more effective. The student who has a need and a desire to learn a skill is easier to teach that skill. The student who plans to make a decision for example, to buy or sell a specific object, is naturally motivated for the lesson and much easier to teach. For this reason, the teacher attempts to gear his instructional program, as far as feasible, to the interests and needs of his students. The time of year and the general order that certain jobs are done in industry should influence when and how jobs are taught.

C8 688

Relaxed.

Confident.

Alert.

Prepared.

THE START IS THE FIRST STEP TO SUCCESS.

1. Be on time! Start on time!

2. Demand attention.

3. Insist on routine in handling books. tools. seating. etc.

4. Curtail preliminaries to the essentials. Get with the lesson.

5. Let students know *objectives* and the *why* of the lesson and what is expected of them.

6. Involve students.

FOLLOW YOUR PLAN!

The means of hitting the home run and touching all of the bases –

1. Have in front of you – try to stick to it.

2. It should be a road map for the lesson. Be cautious about detours.

3. If followed the student should hit the high lights and know at the end what he should have learned.

4. It should lead to a natural summary – approved practices, skills, abilities and knowledge learned.

5. Continual evaluation and revision for later use is necessary.

OBSERVE YOUR STUDENTS

Watch students closely. An alert teacher can determine the following by observation of his class:

How fast to proceed.

Whether or not students are learning.

Fatigue.

Physical conditions of the room.

If directions or assignments are being followed.

Interest or lack of interest.

Special student problems.

Students' reactions help a teacher make certain responses in his own behavior – as loudness of voice, repeat questions or directions, etc.

MAKE MAXIMUM USE OF TIME!

Plan activities on basis of available time.

Plan time for:
.... Class, group, and individualized instruction.
.... Motivational and interest promotion.
.... Summary, testing and evaluation.
.... Next assignments and future activities.

Save teacher and student time by:
.... Formulating with the class, group, or individual – goals, ways and means that activities are to be accomplished.
.... Giving needed instruction before an activity.
.... Developing time schedules for completion of progressive steps and final completion of the project.
.... Providing superior demonstrations, supervision, and evaluation of student work.

The master teacher never seems to have enough *time* – the inferior teacher has too much. The master teacher provides *leadership* and *anticipates problems*. The inferior teacher runs late and spends his time in correctional measures.

STEP I

PREPARATION OR INTRODUCTION STEP

Step 1

Prepare the Learner

Put him at ease.

Find out what he already knows about the lesson at hand.

Get him interested in learning the lesson.

Place learner in correct position to receive instruction.

Explain the value or worth that new knowledge or skill will be to the learner.

HOW TO TEACH

STEP II

PRESENTATION STEP

Step 2

Present the Lesson (following the "Lesson Breakdown and Plan Sheet.")

Tell, show, illustrate, and question carefully and patiently.

Stress key points.

Instruct clearly and completely, taking up one point at a time – but no more than can be mastered.

HOW TO TEACH

STEP III

APPLICATION OR TRY-OUT STEP

Step 3

Application or try out

Test learner by having him present the lesson.

Have learner tell and show you.

Have learner explain key points of the lesson.

Ask questions and correct errors.

Continue until you know HE knows.

HOW TO TEACH

STEP IV

CHECKING, TESTING, and FOLLOW-UP STEP

Step 4

Checking, Testing, and Follow-up

Put him on his own.

Check frequently.

Designate to whom he goes for help or source to get help.

Encourage questions.

Get him to look for key points as he progresses.

Taper off extra coaching and close follow-up.

CHAPTER VII
EVALUATION AND TESTING

EVALUATION OF THE INSTRUCTIONAL PROGRAM

Evaluation is simply an appraisal of outcomes and results in terms of objectives planned. An activity or accomplishment must have happened prior to an evaluation. It is a means of determining the following:

a. Student grades.
b. Teaching effectiveness.
c. Instructional program effectiveness.

Systematic evaluation of pupil progress is an essential part of the teaching-learning process pertaining to any educational objective. Evaluation is most effective when many procedures and devices are used to obtain objective evidence of changed behavior on the part of the learner.

The process leading to the eventual determination of outcomes and results should proceed in about the following steps. The teacher:

1. Determines objectives.

The teacher should evaluate each lesson or each operation to determine the amount of student learning. In order to do this, the objectives must be known. Objectives should be stated as end products. What skill, ability, or knowledge was the student to have learned from the class. The objectives should be worded so they may be observed and measured. Review pp. 30-32. Teaching effectiveness can be measured by the quantity and quality of student learning.

2. Determines standards or criteria to appraise the quality of student work.

Evaluation involves setting standards of work. The quality of work obtained is related to the teacher's ability to set standards and get students to understand and do them. The teacher should grade according to the standard. Without formulation of predetermined standards, there cannot be effective teaching or grading. The student should be constantly aware of his progress. When a student can evaluate his own work on the basis of the criteria established, he is making real progress in learning.

3. Supervises student performance in light of predetermined objectives, standards and instruction given.
4. Evaluates results or outcomes in light of predetermined objectives and standards.
5. Takes action. The following may result: (1) Grades or a rating may be assessed and recorded. (2) Activities may be revised, abandoned or continued.

The most reliable criterion for evaluating vocational education is accomplishment on the job. Where the student cannot perform under actual job conditions, the skilled teacher can simulate most actual job situations in the school.

Teacher effectiveness can be measured by pre-testing and post-testing. This procedure will give the teacher a basis for determining what the students have learned from a unit or course.

Many types of programmed instructional units have been recently developed which provide a means of pre-testing and post-testing. These tests can be of great assistance to the teacher in teaching certain units. Another value of pre-testing before teaching a unit will assist the teacher in planning the instructional program so he will spend time on the subject matter that students do not know. Constant appraisal of teaching procedures will assist the teacher increase his effectiveness. Thus he can eliminate those methods which do not get results.

In determining student grades, the teacher should use a variety of written tests. Usually short tests given once a week are more effective than term tests. The questions should measure a student's ability to think and make judgments rather than straight recall. Test questions should be formulated with a specific objective in mind. The student's response should indicate the degree of understanding of the principle tested. If the objective of the test is to evaluate student learning, it should do just that. The teacher should study student test scores on each question and eliminate those questions which do not measure student learning. Questions that all students get perfect scores on or all students miss should usually be eliminated.

For best results test questions should be completed when the lesson plan is written. This will assist the teacher predetermine what is most important. It will help the teacher measure student learning on the basis of predetermined objectives. All types of tests have value, but multiple choice type tests usually have most of the qualities desired. Well thought out test questions should be saved and used from year to year.

EVALUATION OF A DEPARTMENT

An evaluation can be made on the department as a whole or on one activity.

An evaluation of a vocational department can be best done by using qualified outside individuals to help the teachers in the department. Frequent *self evaluation* is also necessary. If properly done an evaluation can be a powerful "tool" for upgrading teacher and departmental efficiency. It is a "tool" to find strengths and weaknesses. To make

an evaluation is to make a judgment. One cannot make a valid judgment unless he has the facts. These facts must be considered in full knowledge of the limitations and strengths of the school as a whole, and the department. There are many factors, such as school support, which directly influence quality teaching. Teachers can only be held responsible for those factors which fall under their control and they can directly influence. For this reason, a department evaluation is more than an evaluation of the teacher.

In making an evaluation, the following steps should be followed:

1. Review teacher objectives, plans and program.
2. Make a study of the situation p. 28. This should include the quality and quantity of the "inputs" that are fed into the school and the "fixed" factors in the school district that have a direct bearing on the quality of the outcomes.
3. Make a critical study of the school as it is related to the department. Teacher preparation, activities, and performance should also be studied. Pages 17 and 18 list some very important factors to be considered in the evaluation.
4. Make a study of the "outputs" or the long time results of the teaching program p. 26. The facts can be best obtained by talking directly to the students and employers, as well as parents, school administrators, and others who observe, over a period of time, the results of the department.

By weighing the facts determined above in light of established criteria for similar successful departments, a reasonably accurate appraisal of the department can be made. After the evaluation, if progress is to be made, changes must be made by the teachers, school administrators and others responsible for the program.

TEACHER RATE YOURSELF

Did you select and use effectively:

___ Lesson plan.

___ Best resource material available.

___ Blackboard, chart stand, etc.

Did you properly:

___ Select your objective for the lesson.

___ Select the most productive method.

___ Give specific instructions.

___ Stress key points.

___ Summarize your lesson.

Do you have a program to:

___ Keep all students productively busy.

___ Use your tools, equipment and facilities for maximum efficiency.

___ Evaluate and record student work.

ABSTRACT - Intended for enlisted personnel of the U.S. Navy and Naval Reserve who are preparing for advancement to AT1 and ATC, this training course on aviation electronics was prepared by the U.S. Navy Training Publication Center, Memphis, Tennessee. Topics are: (1) Aviation Electronics Technician Rating, (2) Aircraft Maintenance Organization, (3) Technical Drawings and Publications, (4) Aviation Supply, (5) Avionics Maintenance Supervision, (6) Maintenance Procedures, (7) Test Equipment, (8) Infrared Detection, (9) Magnetic Amplifiers, (10) Aircraft Computer Applications, (11) Antennas and Propagation, (12) UHF and Microwave Techniques, (13) UHF Communications, (14) Special Circuits, (15) Principles of Radar, (16) Radar Circuits, and (17) Radar Indicators. A film list, electronics symbols, Greek alphabet, and formulas are appended, and a subject index is included. (GB)

BUREAU OF NAVAL PERSONNEL

NAVY TRAINING COURSE

NAVPERS 10318-C

PREFACE

This Navy Training Course is one of a series of training courses prepared especially for enlisted personnel of the U.S. Navy and Naval Reserve who are preparing for advancement to AT1 and ATC.

The Manual of Qualifications for Advancement in Rating, NavPers 18068-B (revised), has been used as a guide in the selection of content for this training course. Trainees should become familiar with the qualifications for advancement in rating prior to starting work on this course.

Of the 17 chapters in this training course, 16 are concerned with the technical aspects of the AT rating. Chapter 1 contains introductory information with which the trainee should familiarize himself before studying the other chapters.

Basic Electricity, NavPers 10086 (current edition), and Basic Electronics, NavPers 10087 (current edition), contain essential background information for the AT rating.

This training course has been prepared by the United States Navy Training Publications Center, Memphis, Tennessee, for the Bureau of Naval Personnel. Credit is given to the Naval Air Technical Training Center, located at Memphis, Tennessee, the Naval Examining Center, Great Lakes, Illinois, and to the Naval Air System Command, for technical reviews.

1968 Edition

707

THE UNITED STATES NAVY

GUARDIAN OF OUR COUNTRY

The United States Navy is responsible for maintaining control of the sea and is a ready force on watch at home and overseas, capable of strong action to preserve the peace or of instant offensive action to win in war.

It is upon the maintenance of this control that our country's glorious future depends; the United States Navy exists to make it so.

WE SERVE WITH HONOR

Tradition, valor, and victory are the Navy's heritage from the past. To these may be added dedication, discipline, and vigilance as the watchwords of the present and the future.

At home or on distant stations we serve with pride, confident in the respect of our country, our shipmates, and our families.

Our responsibilities sober us; our adversities strengthen us.

Service to God and Country is our special privilege. We serve with honor.

THE FUTURE OF THE NAVY

The Navy will always employ new weapons, new techniques, and greater power to protect and defend the United States on the sea, under the sea, and in the air.

Now and in the future, control of the sea gives the United States her greatest advantage for the maintenance of peace and for victory in war.

Mobility, surprise, dispersal, and offensive power are the keynotes of the new Navy. The roots of the Navy lie in a strong belief in the future, in continued dedication to our tasks, and in reflection on our heritage from the past.

Never have our opportunities and our responsibilities been greater.

CHAPTER 1

AVIATION ELECTRONICS TECHNICIAN RATING

This training course is designed to aid the AT2 in preparing for advancement to AT1 and the AT1 in preparing for advancement to ATC. It is based primarily on the professional requirements or qualifications for AT1 and ATC, as specified in the Manual of Qualifications for Advancement in Rating, NavPers 18068 (Series). In preparing for advancement-in-rating examinations, this course should be studied in conjunction with Military Requirements for Petty Officers 1 & C, NavPers 10057 (Series). The latter covers the military requirements for all senior petty officers.

It should be kept in mind that any changes in the professional qualifications occurring after the change 2 revision of the "Quals" Manual may not be reflected in the information given in this course.

In preparing this training course, every effort has been made to cover professional matters adequately and yet within reasonable bounds. It has been designed to give the prospective AT1 or ATC a good working knowledge of all subjects covered by the professional qualifications for advancement. It includes a great deal of new material required as a result of new equipment and new or revised maintenance programs.

Chapter 2 discusses organizational structure, starting at the Department of Defense level and working down to the maintenance department of aviation squadrons. This chapter is primarily concerned with relationships and responsibilities of commands concerned with naval aircraft maintenance.

Chapters 3 through 17 discuss the technical aspect of the rating. Refer to the table of contents for title and sequence of material in these chapters.

The remainder of chapter 1 is devoted to information which should be helpful in preparing for advancement in rating. It is strongly recommended that this material be studied carefully before beginning intensive study of the remainder of the course.

ENLISTED RATING STRUCTURE

The present enlisted rating structure includes two types of ratings: general ratings and service ratings.

GENERAL RATINGS are designed to provide paths of advancement and career development. A general rating identifies a broad occupational field of related duties and functions requiring similar aptitudes and qualifications. General ratings provide the primary means used to identify billet requirements and personnel qualifications. Some general ratings include service ratings; others do not. Both Regular Navy and Naval Reserve personnel may hold general ratings.

Subdivisions of certain general ratings are identified as SERVICE RATINGS. These service ratings identify areas of specialization within the scope of a general rating. Service ratings are established in those general ratings in which specialization is essential for efficient utilization of personnel. Although service ratings can exist at any petty officer level, they are most common at the PO3 and PO2 levels. Both Regular Navy and Naval Reserve personnel may hold service ratings.

AT RATING

The AT1 and ATC ratings are general ratings and are included in Navy Occupational Group IX (Aviation).

The Aviation Electronics Technician rating, at pay grades E-4 and E-5, comprises the two service ratings ATN and ATR. At pay grades E-6 through E-8, there is a single general rating, AT. At pay grade E-9 the Aviation Electronics Technician rating loses its identity; personnel of pay grade E-8 in this rating, along

711

with AECS, AQCS, and AXCS, advance to Master Chief Avionics Technician, AVCM. Figure 1-1 illustrates all paths of advancement for an Airman Recruit to Master Chief Avionics Technician (AVCM), Chief Warrant Officer (W-4), or to Limited Duty Officer (LDO). The advancement paths through the AT ratings are emphasized in the figure. Shaded areas indicate career stages where qualified enlisted men may advance to Warrant Officer (W-1), and selected Warrant Officers may advance to Limited Duty Officer. Personnel in enlisted rates and warrant ranks may advance only as indicated by the lines.

The Manual of Qualifications for Advancement in Rating, NavPers 18068 (Series), states that AT's are responsible for the inspection and maintenance of aviation electronics equipment, except ASW equipment, including the following:

1. Detection, reconnaissance, identification, communication, navigation, display, and special purpose equipment.
2. Target drone and pilotless aircraft equipment.
3. Related equipment and test equipment.

In addition to these duties, the AT's responsibilities include the operation of airborne CIC equipment.

When advanced to AT1 or ATC, even more responsibilities are to be yours. As a senior petty officer, you must possess more than technical knowledge. You must assume greater responsibility not only for your own work, but also for the work of others who serve under you. The AT1 and ATC must be a supervisor, inspector, and instructor, as well as an accomplished military leader. Senior petty officers should therefore be vitally concerned with the Naval Leadership Program.

As a result of the Naval Leadership Program, a considerable amount of material related to naval leadership for the senior petty officer is available. Studying this material will make you aware of your many leadership responsibilties as a senior petty officer and will also be of great help in developing leadership qualities. It will not in itself, however, make you a good leader. Leadership principles can be taught, but a good leader acquires that quality only through hard work and practice.

As you study this material containing leadership traits, keep in mind that probably none of our most successful leaders possessed all of these traits to a maximum degree, but a weakness in some traits was more than compensated for by strenth in others. Critical self-evaluation will enable you to realize the traits in which you are strong, and to capitalize on them. At the same time you must strive to improve on the traits in which you are weak.

Your success as a leader will be decided, for the most part, by your achievements in inspiring others to learn and perform. This is best accomplished by personal example.

Since the AT rating includes service ratings at the AT3 and AT2 levels, it is necessary to consider the transition from service ratings to the general rating. This is important from the following two points of view:

1. Personnel going from a service rating to the general rating must broaden the scope of their knowledge. For example, an ATN2 cannot advance to AT1 without learning the duties of the ATR2.
2. The AT1 and the ATC have responsibilities for cross-training personnel seeking advancement from a service rating to the general rating.

BILLETS AVAILABLE TO THE AT1 AND ATC

A wide variety of assignments is available to the AT1 and ATC. In addition to the various types of maintenance activities to which lower rated personnel are assigned (discussed in AT3 and 2, NavPers 10317-C), the AT1 and ATC are eligible for assignment to instructor duty as well as a number of other desirable shore billets. Most of these billets are under the management control of BuPers and are directly associated with training. Others are associated with research, testing, or evaluation. Some of the more desirable billets to which the AT1 and ATC may be assigned are described in the following paragraphs.

Instructor duty is available to both the AT1 and the ATC at the Naval Air Technical Training Center, Memphis, Tennessee, in the following schools:

1. Avionics Fundamentals School (Class A).
2. Aviation Electronics Technician School (Class A).
3. Aviation Electronics Technician School (Class B).
4. Aviation Officers School (Class O).

In addition to the above listed instructor billets, the AT1 and ATC may be assigned to instructor duty with a Naval Air Maintenance Training Detachment (NAMTD). NAMTD's are located at shore stations on both coasts. Personnel assigned to this duty are first sent to

712 ۱۱۲

Figure 1-1. —Paths of advancement.

713

Naval Air Maintenance Training Group headquarters at Memphis, Tennessee, for a period of indoctrination and instruction.

Instructor billets are normally filled on a voluntary basis. Detailed information concerning assignment to instructor duty is contained in the Enlisted Transfer Manual, NavPers 15909 (Series).

Chief Aviation Electronics Technicians are eligible for assignment to duty with the Navy Training Publications Center (NTPC), NAS, Memphis, as Technical Writers. CPO's assigned to NTPC assist in the preparation and revision of Navy Training Courses for the Group IX (Aviation) ratings. AT's assigned to these billets assist in preparing and/or revising Navy Training Courses for the avionics ratings.

Chief Aviation Electronics Technicians are also eligible for assignment to duty with the Naval Examining Center, Great Lakes, Illinois, as Item Writers. CPO's assigned to the Examining Center assist in the preparation of Navy-wide advancement-in-rating examinations for enlisted personnel. AT's assigned to these billets assist in preparing examinations for the AT ratings.

There are a number of special programs and projects to which enlisted personnel may be assigned. For a listing of these special programs and projects, reference should be made to the Enlisted Transfer Manual. Others are also announced from time to time in BuPers Notices.

Personnel may indicate their desire for assignment to a specific program or project by indicating it in the "remarks" block of their Rotation Data Card.

As a petty officer, you are already aware of the importance of the AT rating to naval aviation. Pilots and aircrewmen depend upon the AT for the efficient operation of the avionics system for which he is responsible. As improved electronic systems are developed, the AT's job involves new and greater responsibilities; from the lowest level up, he must possess greater technical skills than ever before.

ADVANCEMENT IN RATING

By this time, you are probably well aware of the personal advantages of advancement in rating—higher pay, greater prestige, more interesting and challenging work, and the satisfaction of getting ahead in your chosen career. By this time, alsc, you have probably discovered that one of the most enduring rewards of advancement is the training you acquire in the process of preparing for advancement.

The Navy also profits by your advancement. Highly trained personnel are essential to the functioning of the Navy. By each advancement in rating, you increase your value to the Navy in two ways: First, you become more valuable as a technical specialist in your own rating; and second, you become more valuable as a person who can supervise, lead, and train others and thus make farreaching contributions to the entire Navy.

Since you are studying for advancement to PO1 or CPO, you are probably already familiar with the requirements and procedures for advancement in rating. However, you may find it helpful to read the following sections. The Navy does not stand still. Things change all the time, and it is possible that some of the requirements have changed since the last time you were going up for advancement in rating. Furthermore, you will be responsible for training others for advancement, and so will need to know the requirements in some detail.

HOW TO QUALIFY FOR ADVANCEMENT

To qualify for advancement in rating, a person must:

1. Have a certain amount of time in grade.
2. Complete the required military and professional training courses.
3. Demonstrate the ability to perform all the PRACTICAL requirements for advancement by completing applicable portions of the Record of Practical Factors, NavPers 1414/1 (formerly NavPers 760).
4. Be recommended by his commanding officer.
5. Demonstrate his KNOWLEDGE by passing a written examination on (a) military requirements, and (b) professional qualifications.

Some of these general requirements may be modified in certain ways. Figure 1-2 gives an overall view of the requirements for advancement of active duty personnel; figure 1-3 gives this information for inactive duty personnel.

Remember that the requirements for advancement can change. Check with your educational services office to be sure that you know the most recent requirements.

When you are training lower rated personnel, it is a good idea to point out that advancement

714

ACTIVE DUTY ADVANCEMENT REQUIREMENTS

REQUIREMENTS *	E1 to E2	E2 to E3	#† E3 to E4	# E4 to E5	† E5 to E6	† E6 to E7	† E7 to E8	† E8 to E9
SERVICE	4 mos. service—or completion of recruit training.	6 mos. as E-2.	6 mos. as E-3.	12 mos. as E-4.	24 mos. as E-5.	36 mos. as E-6. 8 years total enlisted service.	36 mos. as E-7. 8 of 11 years total service must be enlisted.	24 mos. as E-8. 10 of 13 years total service must be enlisted.
SCHOOL	Recruit Training.		Class A for PR3, DT3, PT3. AME 3, HM 3			Class B for AGC MUC, MNC.		
PRACTICAL FACTORS	Locally prepared check-offs.	Records of Practical Factors, NavPers 1414/1, must be completed for E-3 and all PO advancements.						
PERFORMANCE TEST			Specified ratings must complete applicable performance tests before taking examinations.					
ENLISTED PERFORMANCE EVALUATION	As used by CO when approving advancement.		Counts toward performance factor credit in advancement multiple.					
EXAMINATIONS**	Locally prepared tests.	See below.	Navy-wide examinations required for all PO advancements.				Navy-wide, selection board.	
NAVY TRAINING COURSE (INCLUDING MILITARY REQUIREMENTS)		Required for E-3 and all PO advancements unless waived because of school completion, but need not be repeated if identical course has already been completed. See NavPers 10052 (current edition).					Correspondence courses and recommended reading. See NavPers 10052 (current edition).	
AUTHORIZATION	Commanding Officer		U.S. Naval Examining Center			Bureau of Naval Personnel		

* All advancements require commanding officer's recommendation.
† 1 year obligated service required for E-5 and E-6; 2 years for E-6, E-7, E-8 and E-9.
\# Military leadership exam required for E-4 and E-5.
** For E-2 to E-3, NAVEXAMCEN exams or locally prepared tests may be used.

Figure 1-2.—Active duty advancement requirements.

INACTIVE DUTY ADVANCEMENT REQUIREMENTS

REQUIREMENTS *	E1 to E2	E2 to E3	E3 to E4	E4 to E5	E5 to E6	E6 to E7	E8	E9
TOTAL TIME IN GRADE	4 mos.	6 mos.	15 mos.	18 mos.	24 mos.	36 mos.	36 mos.	24 mos.
TOTAL TRAINING DUTY IN GRADE †	14 days	14 days	14 days	14 days	28 days	42 days	42 days	28 days
PERFORMANCE TESTS			Specified ratings must complete applicable performance tests before taking examination.					
DRILL PARTICIPATION	Satisfactory participation as a member of a drill unit.							
PRACTICAL FACTORS (INCLUDING MILITARY REQUIREMENTS)	Record of Practical Factors, NavPers 1414/1, must be completed for all advancements.							
NAVY TRAINING COURSE (INCLUDING MILITARY REQUIREMENTS)	Completion of applicable course or courses must be entered in service record.							
EXAMINATION	Standard Exam	Standard Exam or Rating Training.	Standard Exam required for all PO Advancements.		Standard Exam, Selection Board. Also pass Mil. Leadership Exam for E-4 and E-5.			
AUTHORIZATION	Commanding Officer		U.S. Naval Examining Center		Bureau of Naval Personnel			

* Recommendation by commanding officer required for all advancements.

† Active duty periods may be substituted for training duty.

Figure 1-3.—Inactive duty advancement requirements.

716

in rating is not automatic. Meeting all the requirements makes a person ELIGIBLE for advancement, but it does not guarantee his advancement. Such factors as the score made on the written examination, length of time in service, performance marks, and the quotas for the rating enter into the final determination of who will actually be advanced.

HOW TO PREPARE FOR ADVANCEMENT

Preparation for advancement in rating includes studying the qualifications, working on the practical factors, studying the required Navy Training Courses, and studying any other material that may be specified for the rate and rating. To prepare for advancement yourself or to help others prepare for advancement, you will need to be familiar with (1) the "Quals" Manual, (2) the Record of Practical Factors, NavPers 1414/1, (3) a NavPers publication called Training Publications for Advancement in Rating, NavPers 10052 (Series), and (4) Navy Training Courses. The following sections describe these materials and give some information on how to use them to the best advantage.

"Quals" Manual

The Manual of Qualifications for Advancement in Rating, NavPers 18068 (Series), gives the minimum requirements for advancement to each rate within each rating. This manual is usually called the "Quals" Manual, and the qualifications themselves are often called "quals." The qualifications are of two general types: (1) military requirements, and (2) professional or technical qualifications. Military requirements apply to all ratings rather than to any one rating alone. Professional qualifications are technical or professional requirements that are directly related to the work of each rating.

Both the military requirements and the professional qualifications are divided into subject matter groups. Then, within each subject matter group, they are divided into PRACTICAL FACTORS and KNOWLEDGE FACTORS.

The qualifications for advancement in your rating and a bibliography of study materials are available in your educational services office. The "Quals" Manual is changed more frequently than Navy Training Courses are revised. By the time you are studying this training course, the "quals" for your rating may have been changed. Never trust any set of "quals" until you have checked the change number against an UP-TO-DATE copy of the "Quals" Manual.

In training others for advancement in rating, emphasize these three points about the "quals":

1. The "quals" are the MINIMUM requirements for advancement to each rate within the rating. Personnel who study MORE than the required minimum will have a great advantage when they take the written examinations for advancement.
2. Each "qual" has a designated rate level—chief, first class, second class, or third class. You are responsible for meeting all "quals" specified for the rate level to which you are seeking advancement AND all "quals" specified for lower rate levels.
3. The written examinations for advancement in rating will contain questions relating to the practical factors AND to the knowledge factors of BOTH the military requirements and the professional qualifications.

Record of Practical Factors

A special form known as the Record of Practical Factors, NavPers 1414/1, is used to record the satisfactory performance of the practical factors. This form, which is available for all ratings, lists all the military and all the professional practical factors. Whenever a person demonstrates his ability to perform a practical factor, appropriate entries must be made in the DATE and INITIAL columns. As a PO1 or CPO, you will often be required to check the practical factor performance of lower rated personnel and to report the results to your supervising officer.

As changes are made periodically to the "Quals" Manual, new forms of NavPers 1414/1 are provided when necessary. Extra space is allowed on the Record of Practical Factors for entering additional practical factors as they are published in changes to the "Quals" Manual. The Record of Practical Factors also provides space for recording demonstrated proficiency in skills which are within the general scope of the rating but which are not identified as minimum qualifications for advancement. Keep this in mind when you are training and supervising other personnel. If a person demonstrates proficiency in some skill which is not listed in the "quals" but which is within the general scope of the rating, report this fact to the supervising officer so that an appropriate entry can be made in the Record of Practical Factors.

8M17

When you are transferred, the Record of Practical Factors should be forwarded with your service record to your next duty station. It is a good idea to check and be sure that this form is actually inserted in your service record before you are transferred. If the form is not in your record, you may be required to start all over again and requalify in practical factors that have already been checked off. You should also take some responsibility for helping lower rated personnel keep track of their practical factor records when they are transferred.

A second copy of the Record of Practical Factors should be made available to each man in pay grades E-3 through E-8 for his personal record and guidance.

NavPers 10052

Training Publications for Advancement in Rating, NavPers 10052 (Series) is a very important publication for anyone preparing for advancement in rating. This publication lists required and recommended Navy Training Courses and other reference material to be used by personnel working for advancement in rating. NavPers 10052 (Series) is revised and issued once each year by the Bureau of Naval Personnel. Each revised edition is identified by a letter following the NavPers number. When using this publication, be SURE you have the most recent edition.

The required and recommended references are listed by rate level in NavPers 10052 (Series). It is important to remember that you are responsible for all references at lower rate levels, as well as those listed for the rate to which you are seeking advancement.

Navy Training Courses that are marked with an asterisk (*) in NavPers 10052 (Series) are MANDATORY at the indicated rate levels. A mandatory training course may be completed by (1) passing the appropriate Enlisted Correspondence Course that is based on the mandatory training course; (2) passing locally prepared tests based on the information given in the mandatory training course; or (3) in some cases, successfully completing an appropriate Navy school.

When training personnel for advancement in rating, do not overlook the section of NavPers 10052 (Series) which lists the required and recommended references relating to the military requirements for advancement. Personnel of all ratings must complete the mandatory military requirements training course for the appropriate rate level before they can be eligible to advance in rating. Also, make sure that personnel working for advancement study the references which are listed as recommended but not mandatory in NavPers 10052 (Series). It is important to remember that ALL references listed in NavPers 10052 (Series) may be used as source material for the written examinations, at the appropriate levels.

Navy Training Courses

There are two general types of Navy Training Courses. RATING COURSES (such as this one) are prepared for most enlisted ratings. A rating training course gives information that is directly related to the professional qualifications of ONE rating. SUBJECT MATTER COURSES or BASIC COURSES give information that applies to more than one rating.

Navy Training Courses are revised from time to time to bring them up to date. The revision of a Navy Training Course is identified by a letter following the NavPers number. You can tell whether a Navy Training Course is the latest edition by checking the NavPers number (and the letter following the number) in the most recent edition of List of Training Manuals and Correspondence Courses, NavPers 10061 (Series).

Navy Training Courses are designed for the special purpose of helping naval personnel prepare for advancement in rating. By this time, you have probably developed your own way of studying these courses. Some of the personnel you train, however, may need guidance in the use of Navy Training Courses. Although there is no single "best" way to study a training course, the following suggestions have proved useful for many people:

1. Study the military requirements and the professional qualifications for your rating before you study the training course, and refer to the "quals" frequently as you study. Remember, you are studying the training course primarily to meet these "quals."

2. Before you begin to study any part of the training course intensively, get acquainted with the entire course. Read the preface and the table of contents. Check through the index. Thumb through the course without any particular plan, looking at the illustrations and reading bits here and there as you see things that interest you.

3. Look at the training course in more detail, to see how it is organized. Look at the

CU
T718

table of contents again. Then, chapter by chapter, read the introduction, the headings, and the subheadings. This will give you a pretty clear picture of the scope and content of the book.

4. When you have a general idea of what is in the training course and how it is organized, fill in the details by intensive study. In each study period, try to cover a complete unit—it may be a chapter, a section of a chapter, or a subsection. The amount of material you can cover at one time will vary. If you know the subject well, or if the material is easy, you can cover quite a lot at one time. Difficult or unfamiliar material will require more study time.

5. In studying each unit, write down questions as they occur to you. Many people find it helpful to make a written outline of the unit as they study, or at least to write down the most important ideas.

6. As you study, relate the information in the training course to the knowledge you already have. When you read about a process, a skill, or a situation, ask yourself some questions. Does this information tie in with past experience? Or is this something new and different? How does this information relate to the qualifications for advancement in rating?

7. When you have finished studying a unit, take time out to see what you have learned. Look back over your notes and questions. Without looking at the training course, write down the main ideas you have learned from studying this unit. Do not just quote the book. If you cannot give these ideas in your own words, the chances are that you have not really mastered the information.

8. Use Enlisted Correspondence Courses whenever you can. The correspondence courses are based on Navy Training Courses or other appropriate texts. As mentioned before, completion of a mandatory Navy Training Course can be accomplished by passing an Enlisted Correspondence Course based on the training course. You will probably find it helpful to take other correspondence courses, as well as those based on mandatory training courses. Taking a correspondence course helps you to master the information given in the training course, and also gives you an idea of how much you have learned.

INCREASED RESPONSIBILITIES

When you assumed the duties of a PO3, you began to accept a certain amount of responsibility for the work of others. With each advancement in rating, you accept an increasing responsibility in military matters and in matters relating to the professional work of your rating. When you advance to PO1 or CPO, you will find a noticeable increase in your responsibilities for leadership, supervision, training, working with others, and keeping up with new developments.

As your responsibilities increase, your ability to communicate clearly and effectively must also increase. The simplest and most direct means of communication is a common language. The basic requirement for effective communication is therefore a knowledge of your own language. Use correct language in speaking and in writing. Remember that the basic purpose of all communication is understanding. To lead, supervise, and train others, you must be able to speak and write in such a way that others can understand exactly what you mean.

Leadership and Supervision

As a PO1 or CPO, you will be regarded as a leader and supervisor. Both officers and enlisted personnel will expect you to translate the general orders given by officers into detailed, practical, on-the-job language that can be understood and followed by relatively inexperienced personnel. In dealing with your juniors, it is up to you to see that they perform their jobs correctly. At the same time, you must be able to explain to officers any important problems or needs of enlisted personnel. In all military and professional matters, your responsibilities will extend both upward and downward.

Along with your increased responsibilities, you will also have increased authority. Officers and petty officers have POSITIONAL authority—that is, their authority over others lies in their positions. If your CO is relieved, for example, he no longer has the degree of authority over you that he had while he was your CO, although he still retains the military authority that all seniors have over subordinates. As a PO1, you will have some degree of positional authority; as a CPO, you will have even more. When exercising your authority, remember that it is positional—it is the rate you have, rather than the person you are, that gives you this authority.

Training

As a PO1 or CPO, you will have regular and continuity responsibilities for training others.

Even if you are lucky enough to have a group of subordinates who are all highly skilled and well trained, you will still find that training is necessary. For example, you will always be responsible for training lower rated personnel for advancement in rating. Also, some of your best workers may be transferred; and inexperienced or poorly trained personnel may be assigned to you. A particular job may call for skills that none of your personnel have. These and similar problems require that you be a training specialist—one who can conduct formal and informal training programs to qualify personnel for advancement in rating, and one who can train individuals and groups in the effective execution of assigned tasks.

In using this training course, study the information from two points of view. First, what do you yourself need to learn from it? And second, how would you go about teaching this information to others?

Training goes on all the time. Every time a person does a particular piece of work, some learning is taking place. As a supervisor and as a training expert, one of your biggest jobs is to see that your personnel learn the RIGHT things about each job so that they will not form bad work habits. An error that is repeated a few times is well on its way to becoming a bad habit. You will have to learn the difference between oversupervising and not supervising enough. No one can do his best work with a supervisor constantly supervising. On the other hand, you cannot turn an entire job over to an inexperienced person and expect him to do it correctly without any help or supervision.

In training lower rated personnel, emphasize the importance of learning and using correct terminology. A command of the technical languages of your rating enables you to receive and convey information accurately and to exchange ideas with others. A person who does not understand the precise meaning of terms used in connection with the work of his rating is definitely at a disadvantage when he tries to read official publications relating to his work. He is also at a great disadvantage when he takes the examinations for advancement in rating. To train others in the correct use of technical terms, you will need to be very careful in your own use of words. Use correct terminology and insist that personnel you are supervising use it too.

You will find the Record of Practical Factors, NavPers 1414/1, a useful guide in planning and carrying out training programs. From this record, you can tell which practical factors have been checked off and which ones have not yet been done. Use this information to plan a training program that will fit the needs of the personnel you are training.

On-the-job training is usually controlled through daily and weekly work assignments. When you are working on a tight schedule, you will generally want to assign each person to the part of the job that you know he can do best. In the long run, however, you will gain more by assigning personnel to a variety of jobs so that each person can acquire broad experience. By giving people a chance to do carefully supervised work in areas in which they are relatively inexperienced, you will increase the range of skills of each person and thus improve the flexibility of your working group.

CROSS-TRAINING.—Preparing men in service ratings for advancement to the general rating is an important part of your training job. As noted before, the ATN2 cannot advance to AT1 without learning the duties of the ATR2. Similarly, the ATR2 must learn the duties of the ATN2 before he can advance to AT1.

The first step in setting up a program of cross-training is to make a careful study of the qualifications. Suppose, for example, that you are going to train an ATN2 for advancement to AT1. First of all, you know that he will have to be trained in all areas indicated by the qualifications for advancement to AT1. In addition, you will have to make sure that he is trained in all qualifications required for ATR3 and ATR2.

In some cases, of course, third class and second class qualifications are common to both service ratings. For example, "Test, select, and replace circuit parts" is a requirement for advancement to ATN3 and ATR3; consequently, you know that the ATN2 has already been checked out on this qualification. However, the qualification "Energize radar equipment, set indicator controls, and adjust magnetron and crystal current" is required for advancement to ATR3 but is not required for ATN3. Therefore, the ATN2 who wants to advance must learn to adjust radar components.

After you have listed all the ATR3 qualifications that the ATN2 must now learn to meet, group these qualifications into logical units of work or study. Some of the material can be learned by study of the appropriate training course. Other subjects can only be learned by practical experience. Whenever possible, use

regular working situations as training situations. When formal training is required, plan it all out in advance so that you will be able to make the best use of the available time.

Working With Others

As you advance to PO1 or CPO, you will find that many of your plans and decisions affect a large number of people, some of whom are not even in your own rating. It becomes increasingly important, therefore, for you to understand the duties and the responsibilities of personnel in other ratings. Every petty officer in the Navy is a technical specialist in his own field. Learn as much as you can about the work of other ratings, and plan your own work so that it will fit into the overall mission of the organization.

Keeping Up With New Developments

Practically everything in the Navy—policies, procedures, publications, equipment, systems—is subject to change and development. As a PO1 or CPO, you must keep yourself informed about changes and new developments that affect you or your work in any way.

Some changes will be called directly to your attention, but others will be harder to find. Try to develop a special kind of alertness for new information. When you hear about anything new in the Navy, find out whether there is any way in which it might affect the work of your rating. If so, find out more about it.

SOURCES OF INFORMATION

As a PO1 or CPO, you must have an extensive knowledge of the references to consult for accurate, authoritative, up-to-date information on all subjects related to the military and professional requirements for advancement in rating.

Publications mentioned in this chapter are subject to change or revision from time to time—some at regular intervals, others as the need arises. When using any publication that is subject to revision, make sure that you have the latest edition. When using any publication that is kept current by means of changes, be sure you have a copy in which all official changes have been made.

A list of training courses and publications that will be helpful as references and for additional study in preparing for advancement is included in the reading list at the beginning of this text. Additional training courses applicable to the rating are available through your educational services officer.

In addition to training courses and publications, training film furnishes a valuable source of supplementary information. A selected list of training films that may be useful appear in the appendixes of this training course. Other films that may also be helpful are listed in the U.S. Navy Film Catalog, NavAir 10-1-777.

ADVANCEMENT OPPORTUNITIES FOR PETTY OFFICERS

Making chief is not the end of the line as far as advancement is concerned. Proficiency pay, advancement to Senior (E-8) and Master (E-9) Chief, and advancement to Warrant Officer and Commissioned Officer are among the opportunities that are available to qualified petty officers. These special paths of advancement are open to personnel who have demonstrated outstanding professional ability, the highest order of leadership and military responsibility, and unquestionable moral integrity.

PROFICIENCY PAY

The Career Compensation Act of 1949, as amended, provides for the award of proficiency pay to designated enlisted personnel who possess special proficiency in a military skill. Proficiency pay is given in addition to regular pay and allowances and any special or incentive pay to which you are entitled. Certain enlisted personnel in pay grades E-4 through E-9 are eligible for proficiency pay. Proficiency pay is allocated by ratings and NEC's, with most awards being given in the ratings and NEC's which are designated as critical. The eligibility requirements for proficiency pay are subject to change. In general, however, you must be recommended by your commanding officer, have a certain length of time on continuous active duty, and be career designated.

ADVANCEMENT TO SENIOR AND MASTER CHIEF

Chief petty officers may qualify for the advanced grades of Senior and Master Chief which are now provided in the enlisted pay structure. These advanced grades provide for substantial

721

increases in pay, together with increased responsibilities and additional prestige. The requirements for advancement to Senior and Master Chief are subject to change but, in general, include a certain length of time in grade, a certain length of time in the naval service, a recommendation by the commanding officer, and a sufficiently high mark on the Navy-wide examination. The final selection for Senior and Master Chief is made by a regularly convened selection board.

Examination Subjects

Qualifications for advancement to Senior Chief Petty Officer and Master Chief Petty Officer have been developed and published in the Manual of Qualifications for Advancement in Rating, NavPers 18068 (Series). They officially establish minimum military and professional qualifications for Senior and Master Chief Petty Officers.

Training Publications for Advancement in Rating, NavPers 10052 (Series) contains a list of study references which may be used to study for both military and professional requirements.

The satisfactory completion of the correspondence course titled Navy Regulations, NavPers 10740-A, is mandatory for advancement to E-8, and the course titled Military Justice in the Navy, NavPers 10993, is required of all personnel advancing to E-9.

In order to be certain you have the latest "quals," the current NavPers 10052 (Series), and the schedule of advancement examinations, you should visit your educational services office for the latest information.

ADVANCEMENT TO WARRANT AND COMMISSIONED OFFICER

The Warrant Officer program has been revitalized in revised form in the Regular Navy and the Naval Reserve, and is being phased in at this writing (1967). After fiscal 1968, the only rates eligible for advancement to Warrant rank will be E-6's and E-7's. The E-6's must have passed examinations for E-7 prior to selection. After fiscal 1968, enlisted men will have to decide at E-6, or not later than E-7, whether they wish to follow the Warrant or the E-8/E-9 path of advancement.

722
EST

CHAPTER 2

AIRCRAFT MAINTENANCE ORGANIZATION

In order to maintain increasingly complex aircraft in their operating prime, various aircraft maintenance organizations and procedures have been employed throughout the Navy. Prior to and during World War II, it was a general practice for every operating activity to have its own maintenance spaces, equipment, and a complement of maintenance personnel to accomplish all maintenance except overhaul. Due to variance in workload between squadrons, some shops were idle at times and could have been used by maintenance personnel from other squadrons on the same station to accomplish their work.

A combining of talents, efforts, facilities, and equipments for the accomplishment of common tasks was indicated. Through the process of evolution, combining of naval aircraft maintenance personnel and consolidation of maintenance facilities were effected on a Navy-wide basis when the Naval Aircraft Maintenance Program (NAMP) was established.

NAVAL AIRCRAFT MAINTENANCE PROGRAM

The Naval Aircraft Maintenance Program was designed to insure maximum utilization of manpower, material, and equipment and establish standard maintenance procedures and organizations for the accomplishment of maintenance on naval aircraft and associated equipment. The adoption of standard organizations and procedures promotes a high degree of uniformity among all activities in the methods that are used to manage and utilize maintenance personnel, material, and facilities. It results in a decrease in time required to indoctrinate recently assigned personnel.

The improvement of aircraft readiness is of utmost importance; costly, complex weapons systems and spares demand maximum command attention to the repair of critical items to enable aircraft to be in a ready status. It is therefore mandatory that all maintenance personnel have a thorough knowledge of and abide by the established procedures.

LEVELS OF MAINTENANCE

The task of maintaining naval aircraft in an operationally ready condition ranges from a few minutes of squadron servicing to months of overhaul in a depot level maintenance activity. To more efficiently accomplish maintenance on military aircraft the present concept is to divide the maintenance functions into three distinct levels—depot, intermediate, and organizational. The determination of what maintenance will be performed at each level is governed primarily by the availability and distribution of maintenance equipment and facilities.

Each command and support agency is responsible for continually reviewing the distribution of equipment and facilities to insure that the amount of maintenance performed at the lowest levels is consistent with available skills and personnel.

Organizational Maintenance

Organizational maintenance is the type of work performed by the operating squadron or unit on a day-to-day basis in support of its own operations. Maintenance performed at this level includes (1) inspection, (2) servicing, (3) handling, (4) "on-aircraft" corrective maintenance, including removal and installation of parts and components, (5) complying with technical directives (when prescribed), and (6) the necessary recordkeeping and reports peculiar to organizational maintenance.

Organizational maintenance in an operating activity is performed by permanently assigned personnel who are not responsible for intermediate maintenance. Organizational maintenance at shore stations (on aircraft assigned to the station) normally is a function of the Operations Maintenance Division (OMD). The OMD also provides organizational maintenance and such other assistance to transiting aircraft as may be directed by higher authority.

723

Intermediate Maintenance

Intermediate maintenance is that type of work performed in centrally located facilities for the support of operating activities within a designated geographical area, at a particular base or station, or aboard aviation ships. This level of maintenance is assigned for performance to such units as Station Aircraft Maintenance Departments (AMD's), Marine Headquarters and Maintenance Squadrons, Marine Aircraft Maintenance Squadrons, Aircraft Intermediate Maintenance Department (AIMD, afloat), etc. Typical of the work performed at this level is shop type repair and test work on aircraft components and equipment from the supported units. Technical assistance, when required, is furnished by personnel of the intermediate maintenance facility to the supported operating activities.

Intermediate maintenance activities are normally manned by a nucleus of permanently assigned personnel and certain designated intermediate maintenance personnel temporarily assigned from the on-board tenant squadrons. When these squadrons deploy from their home stations, their intermediate maintenance personnel accompany them, and are then temporarily assigned to the AIMD if afloat or to the AMD at their new station.

Depot Maintenance

Depot maintenance is that type of work normally accomplished in an industrial type facility (Naval Air Rework Facilities or contractors' plants.) This level includes overhaul and major repair or modification of aircraft, components, and equipments. It also includes the manufacture of specified aeronautical parts to be stocked as spares and the manufacture of kits for the accomplishment of aircraft and equipment modification. Installation of these spare-parts kits may be done at this or a specific lower level of maintenance.

Navy Depot maintenance activities are manned primarily by civilians. However, some military personnel are usually assigned and assist with the intermediate and organizational type work necessarily connected with the depot facility.

It can be seen from the foregoing that the three aircraft maintenance levels or categories provide for an orderly separation of the various maintenance tasks. The bases for the separation are complexity of the task, equipment and space requirements, the skill level of assigned personnel, and the scope of support responsibility.

FUNCTIONS RESPONSIBILITIES

Functions relate only to the maintenance level authorized to perform the task and have no bearing on the rating or skill required. Some levels will require more than one skill or rating to accomplish its task. Allowance lists for support equipment, tools, and material reflect these maintenance level assignments. The depth and complexity of the specific function will vary with the number and type of aircraft involved.

The Chief of Naval Operations assigns maintenance responsibilities to the operating forces, and the Naval Air Systems Command assigns maintenance responsibilities to the activities ashore under its control. Some activities may be assigned intermediate level maintenance responsibility for an entire logistic area if requested by the cognizant controlling custodian. Specific activities designated to perform intermediate maintenance are authorized to perform higher level maintenance on systems and equipment unique to the assigned mission, and certain other organizational level activities are authorized to perform selective functions in partial intermediate support of their own operations.

SHORE STATIONS

Navy activities ashore assigned intermediate level maintenance responsibilities establish an Aircraft Maintenance Department, usually referred to an AMD. Those activities with assigned aircraft establish a maintenance division within the operations department to perform organizational maintenance on assigned aircraft and on transit aircraft. Intermediate level maintenance activities perform maintenance in support of station aircraft and tenant squadrons and units. The intermediate activity also provides facilities and equipment for tenants to accomplish organizational maintenance. Tenant activities aboard shore stations furnish personnel to the intermediate activity for the accomplishment of its responsibility, and the personnel are used only in the normal spectrum of their individual rate or rating.

All Naval Air Reserve Training Units (NARTU's) and Naval Air Reserve Maintenance Units (NARMU's) are responsible for intermediate and organizational maintenance on their assigned aircraft; however, the supporting activity is responsible for logistic support. Naval and Marine air reserve squadrons are responsible for organizational maintenance on their

724 LST

assigned aircraft while on active duty or assigned to a fleet unit. During regular scheduled drill periods, maintenance is performed according to the training requirements.

SHIPS

For discussion purposes this topic includes aircraft carriers and other aviation ships (AV's, ARVA's, and ARVC's).

Aircraft Carriers

The need for establishing an Aircraft Intermediate Maintenance Department was recognized by CNO and supported by fleet commanders. Therefore, this department is being established in all aircraft carriers (less the one operating with NATRACOM), assigning intermediate maintenance responsibilities afloat to the AIMD instead of the Air Wing/Group Commanders. (See fig. 2-1.) This action dissolves the V-6 division, assigning those functions not directly related to intermediate maintenance to appropriate departments. Squadron maintenance personnel will be assigned to the AIMD as for the AMD previously discussed.

Other Aviation Ships

These ships are responsible for performance or organizational maintenance on assigned aircraft. If aircraft are operated from the ship, intermediate level maintenance facilities are provided air groups, squadrons, and units. Aircraft repair ships (ARVA/ARVC) are assigned intermediate level maintenance responsibility.

INTERMEDIATE LEVEL MAINTENANCE ACTIVITY ORGANIZATION (AFLOAT)(5)

NOTES: (1) WHEN EMBARKED.

(2) AND (3) THE AIRCRAFT MAINTENANCE DEPARTMENT OFFICER (AFLOAT), DEPENDENT UPON HIS SENIORITY, WILL BE ASSIGNED AS EITHER THE INTERMEDIATE MAINTENANCE OFFICER OR MAINTENANCE/MATERIAL CONTROL OFFICER FOR CUSTODY/CONTINUITY PURPOSE UPON DEBARKATION OF THE AIR WING.

(4) BRANCH OFFICERS WILL BE TAD FROM AIR WING/GROUP THE IMA FOR MANAGEMENT RESPONSIBILITIES.

(5) APPLICABLE UNTIL ESTABLISHMENT OF AIMD DIRECTED BY CNO MESSAGE 151806Z MAY 1967

Figure 2-1.—Intermediate level maintenance activity organization, afloat.

725

Nonaviation ships operating or tending aircraft are not assigned maintenance responsibility; however, they provide intermediate and organizational maintenance facilities, support equipment, and material for embarked units.

SQUADRONS

Navy squadrons and units are responsible for performing organizational maintenance on assigned aircraft, with the exception of VRF squadrons. The station supporting activity performs their organizational and intermediate maintenance. All squadrons are required to provide personnel for temporary assignment to the station aircraft maintenance department responsible for squadron support; or if the squadron is deployed aboard ship, the personnel are assigned temporarily to the AIMD, who is responsible for intermediate maintenance support.

AIRCRAFT MAINTENANCE DEPARTMENT ORGANIZATION

The organization for Aircraft Maintenance Departments provide firm lines of authority from the maintenance officer to personnel accomplishing the work for which the department is responsible. The term "department" used in this training course is used as a general term which applies fully to all maintenance activities having a department head. In cases of maintenance activities assigned as divisions to other departments, the next echelon (division) is used in place of department. Branches become sections, and sections become units.

Major segments of the department are called divisions. Divisions are subdivided into branches and branches are subdivided into sections if necessary. The aircraft maintenance officer manages the department and is responsible to the commanding officer for the accomplishment of the department's mission.

The Aircraft Maintenance Department supports naval operations by the upkeep of assigned and supported aircraft and associated support equipments to the level and depth of maintenance assigned. Specific functions include the following:

1. Periodic maintenance and routine inspection and servicing of aircraft, associated support equipment, and aeronautical material and components including the necessary disassembly, cleaning, examination, repair, modification test, inspection, assembly, and preservation.
2. Special work in compliance with technical directives or local instructions.
3. Correction or discrepancies.
4. Assurance of high quality of all work.
5. Maintenance of records and technical publications.
6. Maintenance and custody of tools and other organizational equipment.
7. Training of assigned personnel.
8. Conduct maintenance and ground handling safety programs.

INTERMEDIATE LEVEL ACTIVITY

The primary purpose of this level maintenance is to support and supplement the work of organizational maintenance activities. These functions are normally performed in centrally located areas for the support of operating aircraft on a shore station, aboard a ship, or within a designated area.

The responsibility for intermediate level maintenance is assigned to station aircraft maintenance departments ashore and aircraft intermediate maintenance departments afloat and encompasses the following:

1. Repair and test of aircraft components requiring shop facilities not available in a lower level maintenance activity.
2. Aircraft changes and modifications.
3. Reporting and keeping of records.

Figure 2-2 illustrates an intermediate level maintenance activity, including work center code numbers. As can be seen in the figure, the activity is composed of staff and production divisions.

Maintenance/Material Control Officer

The Maintenance/Material Control Officer is directly responsible to the Maintenance Officer for the management of the overall productive effort of the department. His general responsibilities include but are not limited to the following:

1. Scheduling, coordinating, and monitoring the workload of the department.
2. Maintaining liaison with supported/supporting activities and the local supply department to insure material requirements are fulfilled in order to keep productive capacity compatible with workload requirements.
3. Coordinating the order, receipt, and delivery of material, the administrative screening,

NOTES: (1) WHEN ASSIGNED

(2) QUALIFICATION WILL BE PERFORMED BY THE TEST EQUIPMENT BRANCH OF THE AVIONICS DIVISION.

(3) WORK CENTERS WILL BE ESTABLISHED IN ACCORDANCE WITH APPENDIX "D" OF THE 3-M MANUAL.

Figure 2-2.—Intermediate maintenance activity, ashore.

scheduling, and control of processed components, and the control and usage of funds provided the department.

In discharging the duties of production control, the Maintenance/Material Control Officer will perform the following:

1. Plan and schedule the workload so as to insure maximum utilization of personnel, material, and resources.
2. Coordinate the actions of the production divisions to insure prompt movement of components through the department.
3. Assign production control numbers, work priorities, due-in and due out dates to the various work centers, and establish maintenance control procedures in order to effectively monitor the daily workload requirements.
4. Maintain technical directive control procedures for the department.
5. Review and approve work requests from supported activities.
6. Maintain files of completed maintenance action forms and work requests (6 months).
7. Maintain the Intermediate Maintenance Control Register.
8. Recommend and control cannibalization in accordance with applicable directives.
9. Submit reports as applicable.
10. Analyze daily and monthly maintenance data reports to ascertain effective utilization of personnel resources.

An assistant to the Maintenance/Material Control Officer will discharge the duties of material control by performing the following:

1. Plan, requisition, and expedite materials to enable the department to perform its mission quickly and effectively.
2. Pass all requirements for material for support of weapons system maintenance to the supporting SSC (Supply Support Center), and maintain a material control register for these items.
3. Establish delivery-pickup points for all material as mutually agreed upon by the Supply and Maintenance Officers. Insure that material received is expeditiously routed to the applicable work center.
4. Furnish technical advice and information to the supply activity on the identity and quantity of supplies, spare parts, and materials required for maintenance actions.
5. Establish procedures to insure the periodic inventory of tools and the adequate accountability of material and equipment.

6. Initiate surveys in the event of loss, damage, or destruction of accountable material.

7. Keep the Maintenance/Material Control Officer advised of the overall supply situation as it affects the department.

8. Verify Aircraft on Work Stoppage (AOWS) requisitions and prepare necessary reports in accordance with chapter IV of the 3-M Manual.

9. Perform cost and allotment record accounting, charting, and budgeting of costs applicable to the department.

10. Monitor the operation of toolrooms and maintain an updated IMRL (Individual Material Readiness List).

11. Arrange for return of prospective F condition or R/S material and locally repaired RFI material to supply.

12. Operate an administrative screening unit in accordance with chapter IV of the 3-M Manual.

13. Retain material within the department that is in AWP status until such time the requisition is filled and continually ascertain followup status on same.

Staff Division

Staff divisions are incorporated into the framework of aircraft maintenance activities for the purpose of providing services and support to the production divisions. A discussion of some of the more important functions of the staff divisions is contained in the following paragraphs:

ANALYSIS DIVISION. — The Analysis Division provides qualitative and quantitative analysis information to the Maintenance Officer in order to enable him to continually review the management practices within his organization by accomplishing the following functions:

1. Managing, coordinating, and monitoring the MDCS (Maintenance Data Collection System) for the department.

2. Reviewing MDR (Maintenance Data Reports) to discover and point out workload inequities, personnel inequities, and resource inequities.

3. Collecting, reviewing, and delivering source documents to data services for processing. Picking up complete data reports and disseminating throughout the organization.

4. Maintaining an adequate supply of manuals, source documents, registers, etc., on hand to insure continuity in the MDCS.

5. Developing an analytical plan which encompasses all maintenance functions to provide periodic audits of work center performance.

6. Developing charts, graphs, and displays for command presentations.

7. Maintaining an updated master roster for the department.

8. Coordinating and insuring that 3-M training services are provided to assigned personnel.

ADMINISTRATION DIVISION. — The standard organization structure for intermediate maintenance activities provides an administration division. (In activities where organizational is the highest level of maintenance performed, the organization structure does not provide for a separate administration division. In such activities the functions of the administration division are the responsibility of the Assistant Aircraft Maintenance Officer.)

Administration division personnel accomplish the following specific functions:

1. Establish and control a central reporting and record keeping system for all maintenance reports and correspondence.

2. Implement all directives concerning distribution, retention, and disposition of records and reports.

3. Provide clerical and administrative services for the department.

4. Reproduce as necessary and distribute incoming messages and other data.

5. Supervise and coordinate department administrative responsibilities with other departments/divisions as required.

6. Conduct liaison with the Activity's Administration Department regarding department personnel matters.

7. Safeguard and distribute personal mail to department personnel, when appropriate.

8. Make proper distribution of all nontechnical information and publications.

9. Distribute approved locally issued maintenance instructions, reports, and studies.

10. Control classified material (excluding technical manuals and letter type directives) required by the department.

11. Establish and coordinate the department training requirements. Obtain necessary school quotas to support these requirements.

12. Determine requirements for and insure establishment of proper transportation and communication systems to provide complete support of the workload.

13. Assign spaces to the various divisions and establish the responsibility for security and cleanliness of such spaces.

14. Assume responsibility for the cleanliness and security of vacant or unassigned aircraft maintenance spaces.

15. Arrange department participation in joint inspections of facilities assigned to tenant activities especially incident to the departure of a tenant activity.

QUALITY CONTROL DIVISION. —The quality control division provides the department head with the quality status of work accomplished, points up areas that need particular attention, and develops more realistic inspection requirements. Primary functions performed by this division are as follows:

1. Review all incoming technical publications and directives affecting the department to determine their application to quality control.

2. Prepare or assist in the preparation of maintenance instructions to insure that proper direction and emphasis is given to implementing quality control.

3. Maintain the master technical library for the department, including letter type technical directives and control classified technical publications for the department. Insure that each division/branch receives all publications applicable to its work areas and that these are kept current and complete. Where applicable, maintain the Reader-Printer and associated equipment for aircraft models supported.

4. Establish qualification requirements for Quality Control Inspectors and Collateral Duty Inspectors. Review the qualifications of personnel nominated for these positions and endorse nominations to the Commanding Officer via the department head. Maintain a current record of all designated inspectors. Periodically promulgate a list of all designated inspectors by TIMI or command notice.

5. Obtain and utilize appropriate inspection equipment such as lights, mirrors, magnifying glasses, dye penetrant kits, pressure gages, etc. Insure that productive personnel have such equipment available and in use.

6. Periodically accompany Collateral Duty Inspectors on assigned inspections and recheck their qualifications.

7. Insure all work guides, checkoff lists, checksheets, maintenance requirement cards, etc., used to define or control maintenance operations are completed and current prior to issuing to crews/individuals.

8. Review all UR entries, explanations and descriptions to insure they are accurate, clear, concise and comprehensive prior to mailing. Additionally, either Quality Control or Maintenance Officer will sign all UR's.

9. Cause to be inspected all equipment received for use, returned for repair, or held awaiting repair to insure its material condition, identification, packaging, preservation, and configuration are satisfactory and, when applicable, that shelf life limits are not exceeded.

10. Perform inspections of maintenance equipment and precision measuring equipment to insure compliance with calibration and safety instructions.

11. Perform technical inspections of all maintenance equipment and facilities.

12. Provide for the continuous on-the-job training of all inspectors in the techniques and procedures pertaining to the conduct of inspections.

13. When directed or required, provide technical task forces to study trouble areas and submit recommendations for corrective action.

14. Maintain adequate records and data on discrepancies to enable establishment of trends with the specific objective of determining when discrepancies in any area are ascending.

15. Maintain liaison with contractor, NAESU, NavAirSysComRep's, and other available field technical services. Establish and maintain liaison with other maintenance activities and rework points in order to obtain information on ways for improving maintenance techniques, quality of workmanship and quality control procedures.

16. Review maintenance data reports and note unnecessary and/or recurring discrepancies requiring special action.

17. Insure that established standard procedures are observed by production personnel for conducting bench check, test, and repair of components including engines. Periodically check the performance of this work to insure the desired quality level is obtained.

18. Insure the configuration of aircraft components and support equipment is such that all essential/applicable modifications have been incorporated. This necessitates the review of appropriate records.

Production Divisions

The standard organization for intermediate level maintenance activities provides six production divisions. These divisions perform maintenance on aircraft components and equipment for supported activities. The responsibilities and functions of these divisions are described in the following paragraphs.

Functions of Production Divisions.—Power Plants, Airframes, Avionics, Armament Equipment, and Aviators Equipment Divisions will:

1. Perform intermediate level maintenance functions for tenant squadrons/detachments/units and station assigned aircraft.
2. Continuously review the intermediate level shop facilities for adequacy and make necessary recommendations to the Maintenance/Material Control Officer.
3. Initiate requests to Maintenance/Material Control Officer for production control numbers and material.
4. Nominate qualified individuals for designation as Collateral Duty Inspectors when required.
5. Maintain work center registers and master rosters.

The Support Equipment Division will:

1. Initiate action to obtain the authorized allowance of support equipment, including those items which will be subcustodied to tenants.
2. Nominate qualified individuals for designation as Collateral Duty Inspectors when required.
3. Perform intermediate maintenance on all support equipment, including repair of gas turbine powered equipment engines. Avionics support equipment will be maintained by that division.
4. Administer the program for subcustody of support equipment to other divisions of the maintenance department, Operations Maintenance Division and tenant activities. Periodically inspect subcustodied equipment, in conjunction with organizational activities, to insure proper maintenance, operation and use (except for avionics support equipment).
5. Initiate requests to Maintenance/Material Control Officer for production control numbers and material.
6. Maintain work center registers and master rosters.

ORGANIZATIONAL LEVEL ACTIVITY

The responsibility for organizational level maintenance is assigned to operating units on a day-to-day basis—to support their own operations. Maintenance performed at this level includes aircraft servicing, aircraft inspections, minor adjustments, removal and replacement of defective parts and components, limited aircraft changes and modifications, recordkeeping, and reports. Figure 2-3 illustrates an organizational level maintenance activity, including work center code numbers.

Maintenance/Material Control Officer

The Maintenance/Material Control Officer performs the following functions:

1. Scheduling, coordinating, and monitoring the workload of the department.
2. Maintaining liaison with the supporting activities and the local supply department to insure material requirements are fulfilled in order to keep productive capacity compatible with workload requirements.
3. Coordinating the ordering, receipt, and delivery of material, the administrative screening, scheduling, and control of processed components, and the control and usage of funds provided the department.

In discharging the duties of production control (work center 020), he will:

1. Plan and schedule the workload so as to insure maximum utilization of personnel, material, and resources.
2. Assign job control numbers for each reported discrepancy.
3. Maintain the organizational maintenance control register (3 months).
4. Maintain an up-to-date status board.
5. Provide the Operations Department with required aircraft status and configuration information.
6. Maintain technical directive control procedures.
7. Relay discrepancies to work centers with complete information as to status, by the fastest method (i. e., telephone, intercommunications, etc.).
8. Review and approve work requests to the supporting activity. (Maintain completed files.)
9. Recommend and control cannibalization in accordance with applicable directives.
10. Submit reports as required.
11. Receive certain completed source documents from work centers and:
    a. Update aircraft and equipment logs, accessory record cards, configuration forms, and associated documents.
    b. Forward completed forms to data analysis.
12. Receive completed source documents from data analysis after processing and file for historical records.
13. Conduct monthly maintenance meetings and publish a monthly maintenance plan.

ORGANIZATIONAL LEVEL MAINTENANCE DEPARTMENT ORGANIZATION

NOTE: (1) When responsibilities relative to operation and maintenance of ground support equipment are extensive, the Commanding Officer will establish a Ground Support Equipment Branch under the Line Division to coordinate and/or carry out organizational maintenance functions on assigned support equipment.

(2) When assigned.

Figure 2-3.—Organizational maintenance activity.

14. Schedule all periodic and special inspections and insure maintenance test flights are conducted in accordance with applicable instructions.

In discharging the duties of material control (work center 050), he will perform those applicable functions specified under intermediate level maintenance as well as the following:

1. Prepare documents for material required for operational support of weapon systems (i.e., material chargeable to BRAVO funds such as fuel, oil, and flight clothing, etc.) and material carried in SERVMART/JETMART outlets.

2. Verify NORSAIR (Not Operationally Ready Supply Aviation Item Report) requisitions and maintain (by BUNO) current NORSAIR status records.

3. Inventory aircraft upon receipt and transfer. Insure inventory logs entries are updated, authenicated, and corrected.

Staff Divisions

The organizational level activity has only two staff divisions, having no administration division as explained under the intermediate level. The analysis division is the same for both activities; therefore, it is not discussed here. The quality control division is the same as discussed for the intermediate level with the following additions:

731

1. Review "yellow sheets," maintenance data reports, periodic inspection records and note unnecessary and/or recurring discrepancies that may require special action.

2. Insure that standard established practices are observed for conducting ground tests, preflight, postflight, and daily inspections. Periodically accompany check crews, plane captains, or pilots during inspection (minimum, once a quarter).

3. Insure that pilots/crew are briefed prior to each test flight so that purpose and objectives are clearly understood.

4. Maintain current the Type Commander Maintenance Index Record.

Production Divisions

The organizational level activity provides three production divisions, which are subdivided into branches. Each of these branches/divisions performs many maintenance tasks in order for the operating unit to accomplish its assigned mission.

AIRCRAFT DIVISION.—The Aircraft Division is responsible for the accomplishment of the following functions:

1. Supervise, coordinate, and complete periodic maintenance and inspections. (Check crew leaders and such other personnel authorized by the Maintenance Officer will be permanently assigned.) Additional personnel required to perform periodic maintenance and inspections will be made available as required from other production divisions. The Maintenance/Material Control Officer is responsible for insuring that divisions assign qualified personnel for the completion of scheduled maintenance and inspections.

2. As directed by the Maintenance Officer and in conjunction with other production divisions, perform those applicable organizational maintenance functions in those areas relative to assigned branches; i.e., Airframes, Power Plants and Aviators Equipment.

3. Continuously advise the Maintenance/Material Control Officer of the status of work in progress.

4. Insure cleanliness of hangar and assigned spaces.

5. Nominate personnel for assignment as collateral duty inspectors.

6. Initiate requests for maintenance material.

7. Assume custody for tools and support equipment assigned to the Aircraft Division.

8. Interpret applicable directives and prepare, in draft form, maintenance instructions to implement such directives.

9. Recommend changes in techniques to promote maximum ground safety, safety of flight, and operational readiness of aircraft.

10. Carry out an active program for FOD (foreign object damage) control, as established by the Line Division Officer.

11. Initiate requests to maintenance/material control for job control numbers.

12. Provide troubleshooters and aircrew members, as required, and exercise technical supervision over such personnel.

13. Expedite the accomplishment of assigned work through the continuous evaluation of methods and procedures, and incorporate new techniques as appropriate.

AVIONICS/ARMAMENT DIVISION.—The Avionics/Armament Division is responsible for the accomplishment of the following functions:

1. Assign personnel required to accomplish scheduled periodic maintenance and inspections of assigned aircraft. (The Aircraft Division is responsible for the supervision, coordination, and inspections.)

2. As directed by the Maintenance Officer and in conjunction with other production divisions, perform those applicable organizational maintenance functions in those areas relative to assigned branches, i.e., Electronics, Electrical/Instrument, Armament, and Reconnaissance/Photographic.

3. Continuously advise the Maintenance/Material Control officer of the status of work in progress.

4. Insure cleanliness of assigned spaces.

5. Assume custody and accountability for assigned tools and support equipment.

6. Initiate requests for maintenance material.

7. Nominate qualified individuals for assignment as collateral duty inspectors.

8. Interpret applicable directives and prepare, in draft form, maintenance instructions to implement such directives.

9. Recommend changes in methods and techniques to promote maximum ground safety, safety of flight, and operational readiness of aircraft.

10. Initiate requests to maintenance/material control for job control numbers.

11. Provide troubleshooters and aircrew members, as required, and exercise technical supervision over such personnel.

12. Expedite the accomplishment of assigned work by continuous evaluation of methods and procedures and incorporate new techniques as appropriate.

LINE DIVISION.—The Line Division is responsible for the accomplishment of the following functions:

1. Assign personnel, as required, to accomplish periodic maintenance and inspections of assigned aircraft. (The Aircraft Division is responsible for the supervision, coordination, and completion of periodic maintenance and inspections.)

2. As directed by the Maintenance Officer and in conjunction with other production divisions, perform those applicable organizational maintenance functions in those areas relative to assigned branches; i. e., plane captains, troubleshooters, and ground support equipment (when established).

3. Coordination and direction of troubleshooters. Although troubleshooters will normally be assigned from other divisions on a daily basis, the Maintenance Officer may assign personnel permanently to a Troubleshooter Branch of the Line Division. A troubleshooter should accomplish correction of minor discrepancies.

4. Initiate requests to maintenance/material for job control numbers.

5. Provide to pilots/aircrews records of aircraft discrepancies and corrective actions for the preceding 10 flights of the aircraft.

6. Administer the plane captain program.

7. Nominate qualified personnel as collateral duty inspectors.

8. Participate in an active FOD (Foreign object damage) prevention program.

9. Initiate requests for maintenance material.

10. Insure the cleanliness of assigned aircraft and spaces.

11. Assume custody and accountability for tools and aircraft maintenance support equipment assigned to the division/branch.

12. Insure the security and proper ground handling of aircraft and associated support equipment.

13. Recommend changes in methods and techniques to promote maximum ground safety, safety of flight, and operational readiness of assigned aircraft and associated support equipment.

NAVY MAINTENANCE AND MATERIAL MANAGEMENT (3-M) SYSTEM

The 3-M system is a program to insure the highest state of aircraft readiness and reliability at the lowest cost in men, money, and material. In accomplishing this, it must insure that maintenance personnel, equipment, and facilities are utilized to the fullest extent in the performance of maintenance and not wasted in other functions not requiring highly trained maintenance skills nor specialized and expensive maintenance equipment and facilities.

All aircraft weapon systems must be maintained to the maximum extent possible to perform 100 percent of the functions for which they were designed and to accomplish the assigned mission. Anything short of this goal is considered a compromise to readiness which cannot be afforded.

By analyzing maintenance costs and devising techniques to reduce cost wherever and whenever possible, many procedures and unnecessary actions can be minimized or eliminated entirely. Therefore, by doing away with the unnecessary, effort can be concentrated on increased readiness. The 3-M system embraces two broad areas—a Planned Maintenance System, and a Maintenance Data Collection System.

PLANNED MAINTENANCE SYSTEM

The Planned Maintenance System (PMS) is a system of maintenance planning and control that provides for the uniform accomplishment of planned preventive, rather than corrective, maintenance in all aircraft squadrons. A set of Maintenance Requirement Cards (MRC's) is provided for each type of aircraft, based on information in the Periodic Maintenance Requirements Manual (PMRM). The MRC's tell what inspections are to be performed, when and how they are to be performed, the skills, tools and equipment needed, the safety precautions to be observed, and the inspection sequence.

Many separate but interrelated functions and tasks combined to make up the maintenance workload that is required for support of modern aircraft. The times allocated and available for the accomplishment of this maintenance does not allow for all of these tasks to be considered, planned, and performed on an individual basis; therefore, it is necessary that they be combined, sequenced, and phased in the proper order if the overall task is to be accomplished in the most

efficient manner. The best possible use of allocated time, manpower, materials, and funds is mandatory if the maximum potential weapons system availability and utilization are to be realized.

Operating aircraft are subject to a variety of stresses, strains, vibrations, and environments. If not inspected regularly for all defects, the aircraft would soon become inoperable. The correcting of discrepancies and timely lubrication are performed in conjunction with inspections and enable the aircraft to be flown safely until the next inspection.

The most frequent types of inspections which are performed by activities responsible for the maintenance of naval aircraft are described in the following paragraphs.

Daily Inspection

Daily inspections are accomplished between the last flight of the day and the next scheduled flight, if no more than 72 hours elapse between the inspection and the next scheduled flight. If more than 72 hours elapse between the inspection and the next flight, the inspection must be repeated. This inspection is basically a combination of requirements for checking equipment that requires a daily verification of satisfactory functioning, plus requirements that prescribe searching for and correction of relatively minor problems to prevent their progress to a state that would require major work to remedy. Other items which require inspection at intervals more frequent than prescribed for calendar inspections are also included on the daily inspection and are accomplished along with the daily inspection on the day they become due.

Preflight Inspection

A preflight inspection is performed prior to each flight. This inspection consists of checking the aircraft for flight readiness by performing visual examinations and operational tests to discover defects and maladjustments that, if not corrected, would cause accidents or aborted missions. It also includes a check to determine that the aircraft has been properly serviced for the next flight.

Postflight Inspection

A postflight inspection is performed on aircraft at the termination of the flight. This inspection includes the following:

1. Inspecting critical areas of the aircraft for obvious damage.
2. Servicing the aircraft with fuel, oil, oxygen, etc., to help maintain the aircraft in a ready-for-flight condition.
3. Installing of safety devices such as ejection seats and canopy safety pins, landing gear safety pins, and jury struts to maintain the aircraft in a safe condition.
4. Securing the aircraft after the last flight of the day. This includes installing all protective covers and plugs such as intake and exhaust covers, refrigeration and pressurization plugs, pilot covers, static vent plugs, etc.

NOTE: This inspection is no longer accomplished except where locally authorized to satisfy specific requirements.

Calendar Inspection

The calendar inspection is a thorough and searching inspection of the aircraft. It consists of visual and operational checks of sufficient depth of uncover discrepancies or progressive deterioration within the aircraft that could affect safety of mission accomplishment. This type of inspection is divided into two categories—an ODD calendar and an EVEN calendar inspection—and consists of basic requirements plus additional items scheduled for compliance at less frequent intervals.

Most of the items to be inspected at less frequent intervals are divided evenly so that approximately half of the items are checked on the first (ODD) calendar inspection and the remainder are checked at the second (EVEN) inspection. Subsequent inspections repeat the same ODD-EVEN cycle.

Under this system, the appropriate inspection is conducted at the expiration of a specified number of calendar weeks. Figure 2-4 illustrates a squadron inspection interval.

The Calendar Inspection System is an efficient system from a maintenance management standpoint. When aircraft are inspected under this system, the workload planning operation is simplified and the schedule maintenance in process is automatically stabilized.

The first inspection interval subsequent to Navy acceptance of a new aircraft under this inspection system commences on the date or at the time of the acceptance test flight. The first calendar inspection is performed at the completion of this first interval with subsequent inspections performed in sequence as previously mentioned.

Figure 2-4.—Squadron inspection interval.

The first inspection interval subsequent to standard rework commences on the date entered in the Aircraft Logbook by the rework activity certifying accomplishment of the equivalent calendar inspection. The next calendar inspection due is performed at the completion of this first interval and subsequent inspections are in sequence.

During special rework, the rework activity accomplishes all inspections falling due while the aircraft is in custody of the rework activity. Calendar inspections subsequent to special rework, therefore, continue in sequence. All calendar inspections accomplished by rework activities are noted in the Aircraft Logbook and the Aeronautical Equipment Service Record.

CALENDAR INSPECTION PROCEDURES.—Aircraft are inspected on the calendar interval established by current NavAir Instructions or on an adjusted interval as specified by the controlling custodian. Normally, calendar inspections are programed in multiples of calendar weeks, computed from induction date to induction date, irrespective of days consumed performing the individual inspection. Therefore, an aircraft assigned a 17-week interval would be inducted into the next calendar inspection 17 weeks after the original induction day of the week.

The Calendar Inspection System is placed into operation by dividing the number of aircraft in the aircraft allowance into the calendar inspection interval (for example, 13, 17, 21, or 22 weeks) and programing scheduled maintenance inspection requirements accordingly. Activities responsible for the maintenance and upkeep of large numbers of aircraft group them into multiple units for programing purposes.

To meet unusual situations, a plus or minus 1 week, or portion thereof, may be applied to the authorized calendar inspection interval. To enable a ferry flight to the home ship or station after an away-from-home grounding discrepancy of such duration that the calendar interval expired, necessary additional days may be added. However, in each instance each deviation must be approved by the commanding officer or officer in charge, not delegated, and applies only to the immediate inspection due. If unusual circumstances dictate deviations of succeeding calendar inspections, each is computed from the date on which the inspection would have been due if the preceding deviation had not been granted.

To eliminate peaks and valleys in the workload, the overall pattern of inspections of all aircraft should be one of alternating odd calendars and even calendars. Induction of new and reworked aircraft into an established calendar inspection schedule may require repeating or performing an otherwise unnecessary inspection to insure that the scheduled workload pattern remains one of alternating types of inspections. Newly received aircraft are required to be firmly established in the calendar inspection schedule

within a period not to exceed one inspection interval.

Reporting custodians (operating activities) are authorized under current instructions to increase the depth of any inspection but not to decrease it. Whenever the depth of an inspection is increased to meet unusual or special circumstances, the inspection is recorded only as the type which was due in accordance with the programed sequence. Special inspections to an appropriate depth may be ordered by the reporting custodian whenever excessive utilization during the operating interval is considered to have impaired the material reliability or integrity of the aircraft. Such inspections are in addition to programed requirements and in no way affect the requirement for the accomplishment of the next regularly scheduled inspection.

Special inspections specified in the applicable PMRM are performed concurrently with scheduled calendar inspections when the time authorized for the special inspection is not exceeded. When the time interval will be exceeded during the calendar period inspection interval, the special inspection is accomplished as part of the scheduled daily inspection falling nearest to the requirement.

Scheduled replacement of components with stated operating limitations is normally accomplished during the calendar inspection falling nearest the hourly limitation. To facilitate maximum replacement in accordance with the foregoing, a plus or minus 10 percent of the stated operating time is permissible. When the hourly limitation plus or minus 10 percent does not coincide with a calendar inspection, the replacement is usually accomplished during the scheduled daily inspection nearest the hourly limitation.

NOTE: The Component Removal/Replacement Schedule, found in the applicable PMRM, contains a list of components which must be removed and replaced periodically. This section of the PMRM contains the nomenclature, part number or stock number, quantity, technical justification for removal, corrective action required, and replacement schedule of the components which must be replaced.

MAINTENANCE DATA COLLECTION SYSTEM (MDCS)

The Maintenance Data Collection System (MDCS) is a system for collecting, processing, and analyzing maintenance and material data and distributing information to line commanders and material commands to enable them to carry out management functions in support of the operating forces. This system is also referred to as the management system. The primary purpose of this system is to insure that basic data generated by maintenance personnel are recorded only once. This system provides information from the following categories: manhour

accounting, maintenance data reporting, and aircraft statistical data.

Manhour Accounting

The effective use of available manpower is an important function of maintenance management. Manhour accounting is an important part of the MDCS. The purpose of collecting manhour data is to provide management with essential information necessary to more efficiently plan and direct the distribution of assigned personnel.

The Manhour Accounting System is based upon the "exception" principle; that is, only the deviations or exceptions from normal are reported. Through the use of master rosters, electric accounting machine cards, and machine processed reports, the system provides summaries of the hours expended by maintenance personnel during the normal working day or in an overtime status. Basically, the system is designed so that the normal working hours for each person assigned to the maintenance activity are allotted or assigned to work centers by types of labor at the beginning of each reporting period. Exceptions from these normal working hours, or labor types, are reported by use of Manhour Accounting Cards. Data processing machines add or subtract the exceptions reported on the Manhour Accounting Cards from the initial manhour allotment. These exceptions and the working hours allotted at the beginning of the period serve as the basis for the daily and monthly manhour accounting reports mentioned in the foregoing. These reports are forwarded to the maintenance officers and supervisors for validation and utilization. Each supervisor and worker must thoroughly understand the importance of the system, its operation, and the need for continual accuracy.

At the beginning of each reporting period, generally the first of the calendar month, manhours are assigned to every work center to which personnel are assigned. These manhours are based on an 8-hour workday 5 days per week for every person assigned. Not included in these "original assigned manhours" are any hours for work on Saturdays, Sundays, or holidays during the month. If every person assigned to the work center could be continuously employed throughout the month during all the time available for work, there would be no need for manhour reporting, as the time would be accounted for on the various maintenance data collection forms. Since continuous employment is not possible, each worker must report what he did when he was not working during any period in excess of 20 minutes, or approximately three-tenths of an hour.

Maintenance Data Reporting

This category of data embraces the widest range and most complex types of information involved in the Aviation 3-M System. The scope of the data collected is indicated by the descriptive titles of the data collection forms which are used. These data collection forms are commonly called "source documents." These source documents include the Support Action Form (SAF), Maintenance Action Form (MAF) (single and multicopy), Technical Directives Compliance Form (TDCF), and Configuration Control Form (CCF).

Most of these source documents are originated and completed by the production divisions; however, maintenance control personnel assist in the preparation of some of them.

The Maintenance Data Reporting (MDR) system is designed so that each worker, when accomplishing a job, converts a narrative description of the job into codes and enters the coded information on standard source documents. These source documents are collected and forwarded to the data services activity where the information is transferred onto Electric Accounting Machine (EAM) cards. Data services then uses these EAM cards to produce periodic machine reports listing and summarizing the submitted data. These reports are supplied to maintenance supervisors to provide assistance in planning and directing the maintenance effort. In addition, the information on the EAM cards is forwarded to the Central Data Processing Facility which provides data to satisfy the management requirements of type commanders, system commands, and other managers.

The MDR system provides a valuable tool for use by maintenance managers. It was not designed to replace management or supervision. It was designed to assist management, and to achieve this purpose requires strict attention from the worker to the commanding officer. As with the entire MDCS, the key to an effective MDR system is the work center supervisor. This supervisor must understand the system, the proper procedures for using the source documents and registers, and the information he collects from the machine reports. He must assure complete

and accurate documentation and also insure that assigned personnel have received proper training and motivation. It is well to remember that a product from MDR is only as good as the input information, and the input is used to provide management products for the highest levels of Navy Management.

Aircraft Statistical Data

Management control of an operating unit is furnished inventory, flight, and readiness information by this system. Selected information for each aircraft in the inventory of a reporting custodian is prepared and forwarded to Data Services, and this information is used to establish an accurate master file of inventory data within the local Data Services activity. When the master file is established, it is kept current by the submission of Equipment Statistical Data (ESD) Cards, which are the source documents for this system. Figure 2-5 illustrates the Equipment Statistical Data Card reporting flight data. An ESD card is utilized to report inventory information when an aircraft is gained or lost and when there is a change in the reporting status of the aircraft.

Data Services provides various reports containing inventory, readiness, and flight data. Compilation of selected elements or data in a specified format will aid in the preparation of maintenance information and will allow similar type organizations to compare statistics and equipment.

The following paragraphs provide the description of the report to be made.

The Aircraft Master List, ASD-00, is a monthly report reflecting the true inventory condition of assigned aircraft as of 0001 hours the first day of each month. The report lists the permanent unit code, type equipment code, and the assigned aircraft hours for the appropriate NOR (Not Operationally Ready) reporting status for each aircraft. This report provides a means of verifying and/or correcting data contained in the local inventory data bank.

The report is checked for accuracy and completeness using local records of aircraft inventory change transactions which occurred during the previous month. Erroneous or incomplete data should be corrected and the local inventory data bank corrected in accordance with locally established procedures.

The Daily Flight Report, ASD-1, is a detailed listing of all aircraft flight data submitted on ESD cards during the previous working day. The report may contain data for more than 1 day due to extended flights or flights on weekends or holidays. It indicates flight data collected during shipboard operations and shows landing data, departure and arrival times, date, and the duration and purpose of each flight conducted by each aircraft.

This report provides a means of verifying and correcting information in Data Services files. It also provides maintenance managers with a means of monitoring aircraft utilization on a daily

Figure 2-5.—ESD Card (flight data).

basis and can be used as a measure of accomplishment of the previous day's schedule. The report is checked daily for accuracy and completeness by maintenance control personnel. Erroneous entries should be lined out and the correct data inserted, in red, directly above the lined out entry. After correction the report is forwarded to the Data Services activity.

The Daily Aircraft Readiness Report, ASD-2, is a detailed listing of all aircraft NOR and inventory data submitted on ESD cards during the previous working day. Like the ASD-1, it may contain data for more than 1 day. The ASD-2 shows not ready conditions and inventory changes by bureau number. When an aircraft is reported as NOR more than once during the same day, the data for this aircraft is listed in the order the NOR times began.

This report provides a means of verifying and correcting information in Data Services files. It also provides maintenance managers with a means of monitoring operational readiness on a daily basis.

Maintenance managers use this report to identify specific problem areas that degrade the overall readiness condition. The nature of the problem areas identified may determine what action is necessary to improve readiness. Further, this report provides the means of identifying specific aircraft that detract from overall readiness, measuring the impact of scheduled maintenance, unscheduled maintenance, and supply support on readiness, identifying potential ready hours lost to the awaiting maintenance category, identifying systems or components that contribute to NOR conditions, and computing cumulative readiness rates. The report is checked daily for accuracy and completeness, and any erroneous data corrected in the same manner as the ASD-1.

The Monthly Aircraft Readiness and Flight Report, ASD-3, is a summary of all flight and NOR ESD cards submitted during the reporting period. It shows a summation, by bureau number and type equipment, of hours assigned "IN" or "OUT" of a NOR reporting status, NOR hours by category, total flights and flight hours, and flights and flight hours during shipboard operations.

The report aids maintenance managers in their efforts to maintain optimum aircraft readiness and utilization. The format used lends itself to quick analysis of factors that affect aircraft readiness and utilization. This report provides a means to identify the operationally ready rate, not ready hours by reason, awaiting maintenance hours, aircraft lost to an "OUT" of a NOR reporting status, aircraft that continually account for a large portion of NOR hours, the hours flown by each aircraft, the average flight duration, and flights and hours accumulated during shipboard operations.

NOTE: An aircraft is "IN" a NOR reporting status when the status code of the aircraft is A1 through A8, AJ, and AK; B1 through B8, BJ, and BK; and C1 through C8, CJ, and CK, Not Operationally Ready reporting is required only on aircraft "IN" a NOR reporting status. An aircraft is "OUT" of NOR reporting status when the status code of the aircraft is other than listed above. Aircraft are not reported as NOR when "OUT" of a NOR reporting status.

In addition to these standard reports, Reporting Custodians may request special reports from data services. It should be remembered that any information known to exist in ASD files can be obtained in the form of special reports. However, if the information desired is already available in another report, a special report should not be requested. Special reports should not be used indiscriminately because of the additional, and often excessive workload imposed on Data Services personnel and machines.

MAINTENANCE FORMS AND RECORDS

Effective accomplishment of aircraft maintenance requires thorough familiarity with numerous maintenance forms and records. Some of these are discussed in other chapters of this text. Those discussed in the following paragraphs are aircraft status boards and test flight forms used in postmaintenance flight tests.

AIRCRAFT STATUS BOARD

This board is maintained to provide a visual presentation of current status information on all aircraft assigned to an activity. The aircraft status board, such as the one depicted in figure 2-6, should be of suitable size and material to display sufficient information so that interested personnel can quickly ascertain the essential facts.

The size and location of the board will vary with the employment and operating conditions of the particular activity; however, it remains the responsibility of the maintenance control office to maintain the board in a current and up to date status. Additional columns and subcolumns for

AIRCRAFT STATUS BOARD (Sample)

SQUAD. NO.	MODEL	BUNO	UP or DOWN	STATUS CODE	ENGINE HOURS (since overhaul)	ENGINE HOURS (since check)	A/C HOURS (since check)	NEXT PERIODIC INSPECTION		MONTHS IN SERVICE	REMARKS

Figure 2-6.—Aircraft status boards.

rapid reference may be employed to indicate the status of selected components and functional systems as well as replacement times or dates on selected items. When items which have established replacement intervals are selected for the status board, the time at which replacement is required can be effectively displayed by entering in the component column the replacement interval (or the time remaining on the item) plus the aircraft or engine time when the item was installed. Thus, replacement is required when the aircraft or engine time equals the time entered in the component column. For a more effective display, the figure in the component column may be entered in red as the replacement time or date approaches.

POSTMAINTENANCE FLIGHT TESTS

The control and accomplishment of test flights may be a necessary and integral part of a maintenance process. Test flights are those flights performed to determine if the airframe, powerplant, accessories, and items of equipage are functioning in accordance with predetermined requirements while subjected to the intended operating environment. Such flights are conducted when it is not feasible or possible to determine safe and/or required functioning by means of ground or shop tests. (Refer to NavAir Instruction 4700.2 (latest series) for a listing of conditions that require flight tests.)

LOGS AND RECORDS

All activities which have reporting custody of Navy or Marine Corps aircraft have the responsibility to maintain the Aircraft Logbook and associated records for their assigned aircraft in a proper and up-to-date status.

The actual responsibility for the maintenance of the Aircraft Logbook and its associated records have been recently assigned to the Aviation Maintenance Administrationman (AZ) rating. However, since the technician must supply information for many of the entries which are made in the Aircraft Logbook, it is necessary that he be familiar with it.

AIRCRAFT LOGBOOK

The Aircraft Logbook is the record in which all data concerning the aircraft are posted. Information gathered in this log is used to determine the aircraft condition for planning its rework. Accident investigating boards determine

the compliance with directives from it. It reflects a history of all significant events occurring to the airframs, its components, and accessories. It is a legal document of investigations.

NOTE: The Aircraft Logbook has recently been revised and the NavWeps 13090 forms are being replaced by NavAir Forms. Some of the old forms will continue to be used until present stocks are depleted.

The Aircraft Logbook is a hard cover, looseleaf ring binder containing separators and page insert forms. Each separator and page insert is identified by individual slash numbers.

AERONAUTICAL EQUIPMENT SERVICE RECORD

The Aeronautical Equipment Service Record is a nine-part looseleaf log contained within a separate cover and punched for insertion in the Aircraft Logbook ring binder. This record is prescribed for use with aircraft powerplants, propellers, and airborne auxiliary powerplants. When used as a propeller log, it is prepared using the propeller hub as the basic equipment and must accompany the hub throughout its service life.

The Aeronautical Equipment Service Record is initiated by the activity originally accepting the equipment for the Navy. This record is subsequently maintained by the activity having custody of the equipment. Maintenance of this record is similar to that required for the Aircraft Logbook. Although the record is maintained in the Maintenance Control Office, much of the information that must be incorporated comes from the individual shops. General familiarity with the contents of the log and the record by chief and first class petty officers in all aviation ratings is a valuable aid in the development of the spirit of cooperation so vital to the overall maintenance effort.

The Aeronautical Equipment Service Record consists of the following:

1. The cover (NavAir Form 13090/20).

2. Part I - Guarantee Information and Basic Information (NavWeps Form 13090/21A). This part contains information similar to that contained in the first two sections of the Aircraft Logbook.

3. Part II - Custody and Transfer Record.

4. Part III - Equipment Operating Log. This form is generally self-explanatory; however, a few remarks may be helpful as an aid in preparation and maintenance. For instance it should be remembered that "Military" time refers to reciprocating engines and "Afterburner" time refers to gas turbine engines. The form provides for logging of equipment operating time on a preflight, daily, weekly, or monthly basis except that ferry and test flight times are logged separately. This form provides an additional column without a heading which may be used for logging any special information.

Part IV - Inspection Record. The discussion of this form in the section on Aircraft Logbooks also applies to the preparation and maintenance of the form when used as Part IV of the Aeronautical Equipment Service Record.

6. Part V - Record of Rework. This is also a dual usage form and is to be maintained in accordance with those instructions which apply to the Aircraft Logbook.

7. Part VI - Technical Directives. The recording of technical directives in the Aeronautical Equipment Service Record is largely limited to "bulletin" type publications. Separate pages are used for each type directive and all applicable directives are recorded.

8. Part VII - Preservation- Depreservation Record. This part of the Aeronautical Equipment Service Record is another of the forms that is also used in the Aircraft Logbook. The purpose and the maintenance of this form when used as part of this record are basically the same as for the Aircraft Logbook.

9. Part VIII - Miscellaneous. Part VIII is used in the Aeronautical Equipment Service Record for recording pertinent information for which no other place has been provided. Such information includes special test data, abnormal characteristics of equipment, significant damage and/or repair, and authorization for extension of operating intervals.

10. Part IX - Replacement of Assemblies, Accessories, and Major Components. Part IX is another of the forms that is also used in the Aircraft Logbook. This part of the record is screened for information and discarded at time of rework, and a new Part IX is initiated.

AIRCRAFT INVENTORY

In order to maintain an unbroken chain of custodial responsibility incident to the transfer and acceptance of naval aircraft, the Standard

Inventory Log was developed to be used as an instrument of transfer. In the interest of standardization among the Armed Services, the Aircraft Inventory Record has been designed by the Department of Defense for this purpose. Records are being prepared, instead of Logs, for future new production aircraft.

With remote exceptions, no aircraft may now be transferred or accepted without an Inventory Log or Record. On these occasions an inventory of the aircraft and its equipment must be accomplished, based on the items of equipment and material contained in the applicable Log or Record.

Although the Log and Record serve the same purpose, there are some minor differences in their format and categorical listings. In general, the determination as to whether items are, or are not, subject to listing in these publications without regard as to whether they are Contractor or Government furnished and Contractor or Service installed, is governed by the following:

1. Items essential to the execution of the designated missions of the aircraft, such as armament, electronics, photographic equipment (excluding cameras other than for primary missions), and special instruments, are included.

2. Items of equipment which are rigidly fixed and considered to be a basic or integral part of the airframe, such as engines, propellers, wheels, tires, and brakes, are excluded. In the case of the Aircraft Inventory Record, standard instruments are also excluded.

3. Special equipment items essential to the safety or comfort of the crew, such as bedding, life rafts, Thermos bottles, crash axes, and portable fire extinguishers, are included. Comparable items which are personal issue or furnished on squadron allowances are excluded.

4. Loose equipment delivered with the aircraft, such as covers, mooring kits, and jack pads, for which stowage provisions have been incorporated in the aircraft, are included.

5. Items subject to pilferage or readily convertible to personal use, such as clocks, Thermos jugs or bottles, bedding, and first aid kits, are included. Comparable items which are personal issue or furnished on squadron allowances are excluded.

The Standard Inventory Log is subdivided into groups of equipment (e. g., instrument and navigation equipment, armament equipment, and electronic equipment). The components are listed in alphabetical sequence and according to their location in the aircraft, with the exception of the electronics equipment, in which case all components of an equipment are listed in one place regardless of their location in the aircraft. Stock numbers are also supplied for individual items, and are used for ready reference when replacements are required.

The Aircraft Inventory Record includes a sectional breakdown diagram of the applicable aircraft. This diagram consists of a side elevation and/or the plan view of a wing, or in the case of twin-boomed or flying wing aircraft, the perspective view.

To facilitate inventorying, the sections of the diagram are identified by letters, the letter "A" being assigned to the foremost section, "B" to the next, and so on, generally to the rear of the aircraft. The letter "R," as part of the item number, denotes items mounted on the exterior of the fuselage, and the letter "F" denotes items to which access is gained from the fuselage. Subdivisions of sections may be identified by a lowercase letter, such as "Aa," "Ac," etc.

The equipment list portion of the Record is divided into sections, each of which lists the items pertaining to a particular section of the aircraft, as indicated on the sectional breakdown diagram. Within each section, individual items are numbered as nearly as possible in the sequence of their physical location in the aircraft without regard to their relation to specific equipment. Stock numbers are not supplied as part of the equipment listing in Inventory Records.

One Standard Inventory Log in general is issued as applicable to one aircraft model and designates material and equipment peculiar among the various applicable versions and bureau numbers. The Aircraft Inventory Record is issued as applicable to one aircraft for a specific bureau number.

Blank columns are provided on the inventory pages of the Log and Record, in order that transferring and receiving activities may jointly inventory and indicate the quantity of each item ascertained to be on board the aircraft at the time of transfer. A "Receipt Endorsement Log" in the Standard Inventory Log and a "Certificate and Record of Transfer" in the Aircraft Inventory Record are provided so that transferring and receiving activities may sign, indicating by column applicability, the items on board the aircraft.

Upon the transfer of an aircraft, representatives from the transferring and receiving activities jointly inventory and record, in the appropriate column, the quantity of each item which

is ascertained to be on board the aircraft at the time of transfer. When a ferry pilot or a naval vessel is involved in the transfer, two inventories are made, one prior to the ferry flight or embarkation, and one upon completion. In the former instance the ferry pilot or vessel is to be considered the receiving activity, and in the latter instance the transferring activity.

A Report of Inventory Form supplied with the Standard Inventory Log, or the Shortages Form (DD 780-2) in the Aircraft Inventory Record, is generally prepared in triplicate, listing missing items with appropriate remarks. The original signed copy of the form is retained by the transferring activity and filed as a permanent record of transfer.

The second copy of the form is left in the Standard Inventory Log or Aircraft Inventory Record, as the case may be, and delivered along with the Log or Record to the activity receiving the aircraft.

A third copy of the report or shortages form is forwarded to the cognizant major operating command of the transferring activity for information and any appropriate action deemed necessary.

In the case of missing items, the transferring activity makes every effort to locate the missing items or to withdraw from store the replacement items necessary to complete the inventory. If it is impossible to locate or supply the missing items, the notation "Missing items are not available" is placed in the Report of Inventory Form in the Standard Inventory Log or the Shortages Form in the Aircraft Inventory Record. An explanatory statement signed by the transferring representative is placed within this form, indicating the authority for these shortages. On the basis of this statement, the receiving activity may fill the shortages from stock and account for them in the normal manner.

When an aircraft is abandoned or disposed of by scrapping, the inventory log or record may be destroyed by the activity disposing of the aircraft. When the aircraft is transferred to other U. S. agencies, the log or record is transferred also. When sold to a private party, the inventory log or record is forwarded to the Naval Air Systems Command immediately after consummation of the sale and should include the signatures of the last custodian (seller) and the purchaser. In order to provide the buyer with inventory information, the log or record may be duplicated, provided that it includes no classified information.

CHAPTER 3

TECHNICAL DRAWINGS AND PUBLICATIONS

DRAWINGS AND SCHEMATICS

As a senior AT, you will find a twofold use for your ability to properly interpret schematics and drawings. The need to interpret drawings and schematics will continue to be a part of accomplishing your maintenance tasks. In addition you will be required to assist the less experienced men in interpreting schematics. Often when working with the less experienced men, the need for simplified versions of these schematics and drawings will arise.

INTERPRETATIONS

Instruction manuals used by the AT may contain diagrams of various types; among these are schematic diagrams, block diagrams, wiring diagrams, interconnecting cable diagrams, mechanical drawings, and combinations of some of these types. These diagrams are normally used to present a great deal of information in a small space or to clarify complex and detailed written explanations. Your ability to correctly interpret these diagrams will, to some extent, determine the level of technical knowledge and understanding you can achieve.

Schematics

Electrical and electronic schematics will comprise a large portion of the diagrams the technician uses. Symbols are the building blocks of the schematic. The technician should be familiar with the basic symbols from past experience. The increasing use of semiconductors has added new symbols, and future developments will undoubtedly add more. A study of new symbols and a review of the older standard symbols should be helpful to the AT. A list of standard symbols can be found in Military Standard Graphical Symbols for Electrical and Electronic Diagrams, MIL-STD-15-1.

Another basic consideration in schematic interpretation is recognizing specific type circuits. Here again it may be advisable for the AT to review the basic circuits using electron tubes, semiconductors, or the two in combination. The basic training courses (Basic Electricity, NavPers 10086-A, and Basic Electronics, NavPers 10087-B offer one source of review material for these circuits. In addition, two manuals showing preferred military circuits are listed later in this chapter under miscellaneous publications.

Drawings

Included in the drawings used by the AT are block diagrams, signal flow charts, wiring diagrams, and mechanical drawings. As with schematics, the technician will be familiar with some of these drawings from past experience. The use of block diagrams and signal flow charts to present the overall picture of equipment function is widespread. Although these do not contain the details so often needed in accomplishing your maintenance tasks, they are of great value in fulfilling your training responsibilities and in providing overall continuity when working with partial schematics.

Wiring diagrams, especially in some modern aircraft and equipments, have become quite complex. With the emphasis now placed on integrated electronic systems, a review of wire and cable identification markings and symbols used to show the interconnection of units should be useful to most technicians.

The use of mechanical drawings and the inclusion of mechanical functions on electronic diagrams is increasing. This is due, in part, to the increased use of computers and automatic devices (electronically controlled and mechanically operated).

The technician must understand mechanical symbols and basic mechanical principles in

order to correctly interpret these drawings. The basic training courses comprise a source of some useful information in this field.

MAKING SIMPLIFIED VERSIONS

Making simplified versions of drawings is not as new to the AT as some may think. Each time you have drawn a circuit to explain a point about a large schematic, you were in fact making a simplified version of the schematic. The technician may make simplified versions of drawings for various reasons: to explain a portion of the drawing while working with someone; in connection with the formal training program; or quite often as a means of better understanding a complicated drawing himself.

When making a simplified version of a drawing, use standard symbols, especially in drawings used for training.

There are many possible ways to simplify a drawing. The AT must determine why the diagram needs simplification; this reason may indicate how to go about making the simplified version.

Section IV of the Service Instruction Manual for each electronic equipment contains schematics of circuits or sections of the equipment. These are simplified versions of parts of overall schematics which have been redrawn in order to group components of a particular circuit or circuits to facilitate understanding. While simplification is usually thought of as reducing the whole into parts, there are cases where combining drawings makes them more easily understood. In working with inexperienced men it may be necessary to redraw a circuit to more closely resemble the basic circuit of this type.

PUBLICATIONS INDEX

The publications index, as discussed in this section, is composed of the following separate lists and indexes: Navy Stock List of Forms and Publications, NavSup 2002, Section VIII, Parts C and D; and Naval Aeronautic Publications Index, NavAir 00-500A, B, and C. These lists and indexes will provide the AT with a listing of all available aeronautical publications distributed by Naval Air Systems Command. Within the different sections of the index, the AT will find numerical listings as well as cross-reference indexes. Supplements are published to keep the index current.

NAVSUP 2002, SECTION VIII, PARTS C AND D

Part C of this stock list contains a numerical listing, by code number, of available aeronautic technical manual type publications. In addition to the code number, the publication title, security classification, and date of issue or date of latest revision are given. The instructions for using the stock list include an explanation of the code number system used to identify the manuals by subject group. Also included in this section is information on ordering and methods of procurement of publications. Another section of the stock list is devoted to a cross-reference index of Air Force, NavShips, and NavOrd publication numbers to the NavWeps publication numbers.

Part D of the stock list contains a listing of the letter type technical directives. These are grouped by subject matter and, in addition to the same information that is listed for manuals in part C, an effective date is included if applicable.

All titles of publications listed in these stock lists are unclassified unless marked "1" (Confidential) in the column headed SC (security classification). However, this marking is not classification authority. The bimonthly supplement contains information pertaining to changes in classification action on a when occuring basis. This supplement, in itself, is authority for making classification changes on NavWeps publications.

Parts C and D are distributed semiannually—in September and March. A supplement to these stock lists is issued bimonthly. This supplement is cumulative, so the preceding supplements may be destroyed upon receipt of the latest issue. Included in the supplements are lists of new manuals and letter type publications, lists of canceled publications, lists of interim revisions issued, and special notices and corrections to the basic stock list.

NAVAIR 00-500A

Naval Aeronautic Publications Index, NavAir 00-500A, Equipment Applicability List, contains a listing of aircraft components and related equipment (by model, type, and part number) in alphabetical and numerical sequence, with the applicable publications shown in appropriate columns. This index includes both manual type publications and letter type technical directives.

745

the index includes an explanation of the numbering and grouping system used for both types of publications.

The equipment applicability list is issued twice annually—in March and September. Monthly cumulative supplements are issued to provide a listing of new publications distributed during the interval between reissues of the index.

NAVAIR 00-500B

Naval Aeronautic Publications Index, NavAir 00-500B, Aircraft Application List, contains a listing of aeronautic technical publications with respect to their applicability to a specific aircraft. For example, under the heading S-2D every manual type publication pertaining to the aircraft or any piece of equipment installed in the aircraft is listed numerically.

NavAir 00-500B does not list any letter publications. It lists technical manuals dealing with electronics, armament, instruments, accessories, powerplants, aircraft, and certain general publications. The manuals listed in this index are identified by publication code number only. For titles or other information on special publications, refer to NavSup 2002, Section VIII, Part C.

NavAir 00-500B is also issued and distributed twice annually—in March and September.

NAVAIR 00-500C

NavAir 00-500C, Directive Application List by Aircraft Configuration, contains a listing of the active BuWeps Technical Directives with respect to their applicability to an aircraft.

NavAir 00-500C is published twice annually, in January and July. No supplements are issued to this publication.

USE OF PUBLICATIONS

As a first class or chief, your responsibilities in connection with installing, adjusting, maintaining, and testing electronic equipment will be much greater than they were when you were a lower rated petty officer. You will be required to have quick and accurate answers to many questions. Since there is a wide variety of complex equipment, you cannot expect to have a ready answer to all questions. However, you will become familiar with the published materials that contain the answers, and by so doing you will be able to take positive action.

MAINTENANCE INSTRUCTIONS MANUAL

A Maintenance Instructions Manual is distributed for each type of aircraft. Recent manuals are issued with the sections as separate volumes to facilitate the use of the manual by the different shops. The sections concerning electric and electronic systems maintenance and wiring data are of prime interest to the AT.

Location of components and instructions for removal and installation are included in the manual. The wiring diagrams, power distribution charts, and drawings showing the location and connection of fuses and circuit breakers are valuable to the technician while troubleshooting in the aircraft.

Information on electronic equipment maintenance is also included. The amount of this information or the depth of maintenance discussed will vary from one manual to another and also between equipments within a given manual. Included in some manuals for organizational maintenance are operational and functional checks, trouble isolation charts, and adjustment charts. The intermediate maintenance section may contain information for bench checks, troubleshooting, disassembly, repair and parts replacement, and assembly instructions. If special support equipment is needed to accomplish the maintenance described, a section on use and maintenance of this support equipment may be found in the volume on electronic maintenance. These manuals, when used in conjunction with the Service Instruction Manual for the electronic equipment, furnish the technician with information needed to properly maintain the equipment.

OPERATION AND SERVICE INSTRUCTION MANUALS

The Naval Air Systems Command procures Operation and Service Instruction Manuals for various avionics equipments. The Operation and Service Instruction Manuals may be issued as one combined manual or as separate manuals. In some cases, where the equipment is installed in only one aircraft, the Maintenance Instructions Manual for that aircraft will contain the information normally found in the Operation and Service Instruction Manual.

Aviation Electronics Technician 3 & 2, NavPers 10317-C, lists the subject content of each

section of this manual. The discussion in this course will be limited to a few of the items contained in the manual.

Performance Specifications

As a senior AT, your responsibilities for inspecting the work of others will increase. The Operation and Service Instruction Manual contains charts or sections on standards the equipment should meet if it is to be considered as performing satisfactorily. The use of this information to determine the quality of your own work or the work of some other AT is recommended. The preflight checks given in the manual usually give only an indication of overall system operation and do not indicate how much above minimum standards each section is operating. There are some equipments that utilize line testers for this check; line testers quite frequently are of the GO, NO-GO type. This is the most basic of the performance standards the equipment must meet.

The preliminary or preinstallation inspection is normally a bench test procedure for equipment received from the supply system or from an intermediate maintenance activity. Normally, this is also a check for overall operation of the equipment and is not designed to check the equipment for specific circuit performance.

The portion of the manual that gives the performance standards for the individual sections of the equipment is titled "Minimum Performance Checks" or "Specifications." These standards are shop procedures used to check the individual sections of the equipment against the acceptable performance levels. In addition to listing the minimum acceptable performance levels, this section gives procedures for setting up the equipment for test, the test equipment to use, and the adjustments required to bring the equipment up to standard.

The specific checks given will vary with the type of equipment—communications, navigation, or radar. Some checks of the type found in this category are as follows:

1. Receiver sensitivity.
2. Transmitter power output.
3. Signal-to-noise ratio.
4. Bearing or range accuracy check.
5. Receiver recovery time.
6. Frequency tolerance.

Where the equipment fails to meet minimum performance standards, a malfunction is indicated. Trouble analysis charts and alinement procedures are included in the manual to assist the technician in locating and correcting the malfunction.

Adjustments

The Operation and Service Instruction Manual contains charts and instructions for adjusting the equipment. One of these charts will be found in the organizational maintenance section of the manual. The information given will concern minor repairs and adjustments.

The adjustments given in the field maintenance section are more extensive than those in the section on organizational maintenance. Normally included in this section are the complete alinement procedures for each section of the equipment. The instructions include the step by step procedures and give the test equipment setup required.

Special Tools

The Operational and Service Instruction Manual furnishes a list of special tools required for maintaining the specific equipment. The technician should check the applicable allowance list to determine whether the tools are available to his unit as organizational property or if it will be necessary to procure them on custody from the supporting activity.

FILING AND MAINTAINING PUBLICATIONS

A steady stream of technical correspondence, directives, and publications is received by the Avionics Division. A system for filing this paperwork and disseminating the useful information must be established if full value of these sources is to be realized. In order for the information to be of value to the division, it must be brought to the attention of the people in the shop. A routing system within the shop will provide for the dissemination of the information to all personnel concerned.

There is a great deal of technical information received concerning the many pieces of equipment. The file location of this information must be known and accessible, so that the individual assigned to repair or test the equipment will have all the necessary information available.

The avionics shop should establish and maintain a technical library. The shop's technical

747

library should consist primarily of a complete and current set of letter publications and technical manuals which are pertinent to equipments and aircraft serviced by the shop. In addition, it should contain a file of the Digest of U.S. Naval Aviation Electronics, NavAir 08-1-503, and other material of informative or training nature.

The technical library should be kept in an orderly fashion, and its facilities made readily available to all personnel. General and little used material should be filed in the division or shop office, and the manuals should be filed in the shop.

For larger activities, or those where many people utilize the same technical library, it is imperative that a checkout system be instituted for certain publications. This system will enable an interested individual to locate needed publications on board and will also aid in maintaining a complete and current library.

A custody card or logbook system can be developed at the discretion of the Avionics Officer. Regardless of which system is chosen, it should provide information regarding the home unit of the borrower, the date and time of loan, and the security classification of the publication.

Maintaining the manuals in good condition and up to date is very important. If the manuals are abused or mishandled, it is easy to lose pages or otherwise decrease the usefulness of the available information. All revisions should be incorporated as soon as received in order to keep the information correct and current.

MISCELLANEOUS PUBLICATIONS

There are a great number of technical publications, other than the maintenance and service instructions, that the AT will find useful in performing his job. This section lists and describes briefly a few of these publications. By including this type of publication in the shop technical library, the supervisor will be providing information that should increase the efficiency of the shop.

Handbook of Installation Practices for Aircraft Electrical and Electronic Wiring, NavWeps 01-1A-505

This manual was written for the following purposes:

1. To bring together under one cover the recommended practices and techniques to be used for installing, repairing, and maintaining aircraft electric wiring.
2. To standardize these techniques and methods so that electrical/electronic installations are performed in a uniform manner.
3. To indoctrinate all personnel with the importance of good workmanship.
4. To point up the failures which may result from poor workmanship.
5. To promote safety by pointing out and prohibiting unsafe practices.

The information contained in the manual represents the best current knowledge and practice in the avionics field. It has been compiled with the cooperation and assistance of leading airframe manufacturers, airline operators, and military overhaul and repair bases. Many of the illustrations have been provided by the manufactures of electrical accessories used in aircraft.

The following topics are covered:

1. Wire and cable preparation.
2. General purpose connectors.
3. RF connectors and cabling.
4. Solderless terminations and splicings.
5. Thermocouple wire soldering and installation.
6. Bonding and grounding.
7. Bus bar preparation.
8. Conduit fabrication.
9. Installation of bus bars, conduit, junction boxes, protective devices, and terminal strips.
10. Electrical wiring installation.
11. Lacing and typing.
12. Safety wiring.
13. Emergency repairs.

This manual can be of much assistance to the leading petty officers because it contains the answers to many questions. Also, it is an excellent teaching aid in carrying out your on-the-job training duties.

Reduction of Radio Interference in Aircraft, NavAer 16-1-521

The purpose of this manual is to present information which will serve as a guide to the aviation industry and to naval aircraft maintenance activities for reduction of radio interference in naval aircraft. It may be used as a guide to enable you to determine the type of interference, to locate its source, and to provide a means for its elimination or suppression.

35,748

The information is presented under the following headings:

1. Purpose.
2. Types and effects of radio interference.
3. Sources of radio interference.
4. Interference coupling.
5. Basic installation planning for radio interference control.
6. Radio interference reduction components; their selection, application, and installation.
7. Bonds and bonding.
8. Shields and shielding.
9. Testing for radio interference.
10. Maintenance aspects of radio interference.

Handbook of Test Methods and Practices, NavShips 900, 000. 103

This manual is written to meet the technician's need for convenient reference on the fundamentals of testing electronic equipment. The wide scope of information, covering both theory and practice, makes the manual equally valuable for the beginning technician and the technician who has much experience. The manual has been reviewed by technicians in shops and in schools in order to make it as effective as possible. It is presented in five sections as follows:

Section 1, Testing in General, discusses the importance and functional divisions of testing, along with some associated testing information, and explains the need for various types of measurements and tests.

Section 2, Test Equipment and Measurements, provides the technician with a background in test equipment circuit theory. With this background he will be better able to select the most suitable test equipment for a particular job and to interpret correctly the data received. In addition he will be qualified in the use of both general and specialized test equipment. All of these abilities are important requirements for efficient performance testing and troubleshooting.

Section 3, Testing Techniques and Practices, covers in detail the specific procedures used in testing equipments. In this section the selection of test points, the correct interpretation of tests, and the selection of suitable test equipments are stressed as important requirements for efficient testing.

Section 4, Care and Repair of Test Equipment, deals with both preventive maintenance and repair of test equipment. Preventive maintenance procedures, care of accessories and cables, proper storage of equipment, and periodic inspections are all considered important parts of the technician's job.

Section 5, Reference Data, contains data such as a list of the terms used in this manual, tables of radiofrequency classifications, letter coded radar bands, and Smith charts.

Periodic Maintenance Requirements Manual

This manual contains the planned scheduled maintenance requirements for the aircraft concerned and is the controlling document for the planning and accomplishment of the related work tasks through all levels of maintenance.

The maintenance requirements contained in this manual specify the equipments to be inspected or examined and the required conditions. It does not contain instructions for repair, adjustments, or troubleshooting, as this type of information is found in the Maintenance Instructions Manual for the particular aircraft.

The planned maintenance requirements prescribed by the Periodic Maintenance Requirements Manual are considered to be the minimum necessary under any conditions to assure timely discovery and corrections of defects. The listed designated calendar intervals are the maximum authorized based on aircraft class and planned Navy-wide utilization. Due to varying operational requirements, climatic or environmental conditions, squadron commanders may increase the scope or frequency of material inspection or examination as required to properly and safely carry out assigned missions.

Part I of this manual contains sections on maintenance management, definitions, preflight, daily and calendar inspection procedures, and references.

Part II contains fleet maintenance requirement data for daily, calendar, special, and preflight inspections.

Part III includes the requirements for progressive aircraft rework. The first section of Part III contains instructions on squadron responsibility and rework activity responsibility. The rest of the sections are a listing of the systems of the aircraft.

Part IV contains the component removal and or replacement schedule. The replacement time intervals are indicated in operating hours, calendar time, or PAR periods as appropriate. Components are arranged according to systems.

Part V is a listing of the components by part number and nomenclature which require accessory card entry into the appropriate logbook.

Department of the Navy
Safety Precautions for Shore
Activities Nav So P-2455

The purpose of this manual is to present the safety precautions applicable to Navy shore activities including shore (field) activities of the operating forces and fleet schools. The safety precautions given in this manual are of necessity basic and general in nature and are not inclusive of all conceivable operations and functions involved in the great variety of shore activities. In many instances references are made to other publications for detailed safety precautions applicable to specific operations.

The senior AT should become very familiar with the contents of this manual. It is the responsibility of supervisory personnel to see that safety precautions are strictly adhered to. Continuous cooperation and vigilance of all personnel are needed to see that all operating procedures and work methods do not unnecessarily expose personnel to injury or property to loss or damage.

Index of Safety Precautions
OpNav Notice 5100

OpNav Notice 5100 is an index of Navy Department documents containing safety precautions applicable to the operating forces.

The manual, "United States Navy Safety Precautions" (OpNav 34P1), is no longer in use. To assist commanders in the operating forces in carrying out their responsibilities in the area of safety, the Chief of Naval Operations has revised the index of publications, pamphlets, periodicals, and directives, issued by commands and offices of the Navy Department, which address themselves to safety precautions applicable to the operating forces.

Instructions and procedures pertaining to aspects of safety are contained in general and specific manuals such as NavShips 250-000, Naval Ship Systems Command Technical Manuals, Volumes I, II, and III. The safety precautions listed in OpNav Notice 5100 are not intended to replace the instructions in manuals but only to supplement by providing specific safety precautions in certain categories where they have been changed or have been implemented. When the listed precautions references have been included in manuals, they will be deleted from the index. It behooves the senior AT to review this index and to study sections applicable to his activity. As stated previously, it is the responsibility of supervisory personnel to ascertain that all safety precautions, as cited in OpNav 5100, are rigidly enforced.

Aviation Electronics Officer's
Guide, NavAer 00-80T-64

This publication is issued by the Office of the Chief of Naval Operations, Aviation Training Division. It is a compilation of information prepared primarily to assist the naval aircraft electronics officer in the performance of his technical and administrative duties. Since some of the duties of the ATC and AT1 closely parallel those of the electronics officer, this publication can be of use as an excellent source of information.

The major sections of the publication are as follows: introduction to naval aeronautics aeronautics organization; safety; technical duties; reports, records, local directives, and memoranda; supply; publications; education and training; security; and technical reference material.

Handbook Preferred Circuits
NavWeps 16-1-519

This publication is designed primarily for engineering standardization. It does, however, contain information of interest to the AT. Another publication in this category is the Guide Manual of Cooling Methods for Electronic Equipment, NavShips 900, 190.

Semiconductor Device Replacement
Guide, NavWeps 16-1-530

This publication contains replacement technical, and mechanical information on all semiconductor devices listed in the Navy Supply System.

SECURITY OF CLASSIFIED PUBLICATIONS

Security is one of the chief responsibilities confronting the Avionics Division. Although security is the duty and responsibility of all hands, security rests very heavily upon

electronics supervisors because of the classification of the equipments, systems, and publications with which AT's work.

Department of the Navy Security
Manual for Classified Information
OpNavInst 5510-1 (Series)

The objective of the orders and instructions contained in this publication is to establish a coordinated policy for the maintenance of the security of all matter classified in the interest of national defense. The United States Navy Regulations, the Espionage Act, and Atomic Energy Act, executive orders, and other legally established directives form the basis for this publication. These regulations do not restrict the mature judgment of individuals in the proper application of initiative, and local commands may issue additional security instructions as necessary to meet local situations. However, this manual contains detailed procedures and outlines basic responsibilities of the security system. Reference to this manual will provide methods of implementation of the security system for most encountered circumstances. The senior AT should be familiar with this publication.

SECURITY RESPONSIBILITY

Commanding officers are directly responsible for safeguarding all classified matter within their commands and are responsible for instructing their personnel in security practices and procedures. Security consciousness is the duty and responsibility of ALL Navy personnel. As a senior PO, you have the added duty and responsibility to insure that all avionics personnel become security conscious, and that this consciousness be maintained by repeated instructions in matters of security.

HANDLING AND STOWAGE

Handling and stowage procedures concerning classified publications are dependent upon both the classification and the quantities of the particular material to be stored. However, rarely should the Avionics Division maintain in private files any publications classified Top Secret or Secret. When such occurs, strict attention to instructions for handling and stowage of Top Secret and Secret material should be observed.

A checkout system utilizing logbooks or custody cards MUST be maintained for the proper handling of classified publications.

KEYS AND COMBINATIONS

It is essential that combinations or keys be accessible only to those personnel whose official duties demand access to the container involved. The combination to a security container should be changed whenever one of the following conditions occurs:

1. When the combination lock is received.
2. When a person having knowledge of the combination leaves the organizational unit.
3. When there is reason to believe the combination has been compromised.
4. When the lock has not been changed in a 12-month period.

PERSONNEL SECURITY CLEARANCES

Any person having access to classified matter must have a security clearance. NEVER assume the security clearance of anyone regardless of rank or rating or previous activities. Always demand valid proof of entitlement to classified information. Limit access to classified information, and to the files, to a "need to know" basis (information necessary for the performance of the individual's duties). On the other hand, remember that avionics personnel, due to the nature of their ratings and the continual need for updating their education on the latest avionics system, should be properly cleared and have assess to material relevant to the duties of their ratings. Leading petty officers should take the lead in establishing the right balance in this area.

CHAPTER 4

AVIATION SUPPLY

A Chief or First Class Technician, especially if in a supervisory billet, will find himself increasingly involved in the details of supporting the man on the job. One of these detail areas is in the field of aviation supply.

Aviation supply personnel are vital members of the aircraft maintenance team; and the technician as well as the other aviation maintenance ratings must work in close harmony with them if successful teamwork is to be achieved. The team must work so that a flow of parts is maintained from the manufacturer to the man on the job—quite possibly a technician doing repair work on the other side of the world. A correct concept of supply's relationship to the entire organization is essential in the supervision of aircraft maintenance functions.

ORGANIZATION AND FUNCTION OF NAVAL SUPPLY

The command exercising management control over the policies and procedures of the aviation supply organization is the Naval Supply Systems Command. The Commander of the Naval Supply Systems Command is usually a rear admiral who is appointed by the President for a term of 4 years with the advice and consent of the Senate. He works with the delegated authority of the Secretary of the Navy and all orders emanating from him have the full force and effect of SecNav orders.

To better understand the relationship of the Naval Supply Systems Command to the Aviation Supply System it might be well to quickly review the development of the Navy Supply System. Prior to 1842 the commanding officers of ships and stations were responsible for the procurement of their own supplies. They were furnished funds for this purpose by the Navy Department and were required to account for all expenditures. In addition to creating an intolerable burden of paperwork on the Navy Department this procedure had the effect of forcing prices upward, especially when two commanding officers were bidding for some scarce commodity.

In 1842 Congress approved the establishment of a Bureau of the Navy to take cognizance over all matters of naval supply. The primary responsibilities of this infant supply bureau were the procurement, maintenance of custody, and issuance of naval material. They are the primary responsibilities of the Naval Supply Systems Command today. Every function of the Naval Supply Systems Command is directly related to one or more of these responsibility areas.

In the early years of naval aviation when the Navy had few aircraft, the procurement of spare parts was much like the old system whereby commanding officers dealt directly with the sellers to fill the needs of each command. The pioneer naval aviation project directors had to deal directly with the manufacturers as parts were required.

By 1917 the Naval Aircraft Factory (NAF) in Philadelphia had come into existence and was assigned responsibility for the procuring of aircraft and spare parts. Other responsibilities assumed by NAF included the repair of aircraft, the manufacture of some spare parts, and eventually the manufacture of complete aircraft. There are still many aviators around today who earned their Navy wings in the old N3N, built by NAF.

In 1921 the Bureau of Aeronautics (BuAer) came into being and assumed the responsibility of procuring aircraft and aircraft engines. The responsibility for procuring spare parts and other aeronautical material remained with NAF, which until 1941 was the aviation supply center of the Navy.

The Aviation Supply Office (ASO) was established in 1941 under the technical control of BuAer and the management control of BuSandA. The function of ASO was the procurement, custody, and issuance of aeronautical spare parts and technical material. This is essentially the

function of ASO today under the technical control of the Naval Air Systems Command. Management control is still vested in the Naval Supply Systems Command.

RESPONSIBILITIES OF THE NAVAL SUPPLY SYSTEMS COMMAND

The general functions of the Naval Supply Systems Command within its areas of responsibility include many that are not of primary interest to aviation personnel in that they are not related to aircraft maintenance. Listed below are some of the more important general functions of the Naval Supply Systems Command.

1. Supervises the procurement, receipt, custody, warehousing, and issuance of Navy supplies and materials, exclusive of ammunition, projectiles, mines, explosives, and medical supplies.
2. Supervises and directs the operation of the supply phases of the Navy Supply System and administers the redistribution program of excess personal property within the Department of Defense and the sale of Navy surplus property.
3. Authorizes and supervises the transportation of Navy Property.
4. Prepares budget estimates and administers funds for the supply distribution system.
5. Renders an annual report to the Congress of money value of supplies on hand at the various stations at the beginning of each fiscal year, the disposition thereof, purchase and expenditure of supplies for the year, and balance on hand.
6. Coordinates the compilation and arranges for the printing of the Catalog of Navy Material.

Some additional functions of the Naval Supply Systems Command that are of interest to naval aviation maintenance personnel are the general functions of ASO. These include the following:

1. Responsibility for overall determination of requirements, procurement, and distribution of standard aeronautical materials. (Certain materials excepted; e. g., complete aircraft and engines, complete electronic equipment, major photo equipment, nonstandard and experimental aerological equipment, and items of naval weapons ordnance equipment.)
2. Maintenance of a complete file of ASO and Naval Air Systems Command contracts, letters of intent, amendments, extensions, and change orders, and distribution of copies of documents necessary to Navy field activities.
3. Stock control of aeronautical materials at all aviation supply facilities, including control of packing, preservation and distribution of material under ASO cognizance to, from, and between aviation supply facilities and major supply points.
4. Maintenance of complete records of material on order and followup procedure necessary to effect timely deliveries for all material under ASO cognizance.
5. Maintenance of up-to-date records of existing storage facilities at depots, major supply points, and operation stations for aeronautical materials, and control of influx of materials in aviation supply channels so as not to exceed existing storage facilities.
6. Determination and disposition of obsolete and excess aeronautical material under the Naval Air Systems Command cognizance.
7. Preparation and distribution of the Navy Stock List of the Aviation Supply Office, including interchangeability data.
8. Compilation and distribution of some allowance lists subject to approval by the Naval Air Systems Command.
9. Compilation of lists of spare parts to be salvaged from surveyed aircraft.
10. Followup on delivery, stock recording, reallocating as necessary, and distributing change material promulgated by the Naval Air Systems Command.
11. Establishment and maintenance of a statistical unit which assembles, compiles, and analyzes usage data.
12. Maintenance of a representative at each aircraft manufacturer's plant who keeps ASO fully informed, as requested, as to all changes which affect spare parts under procurement.
13. Establishment of an inspection service which inspects aviation supply activities within established naval districts.

APPROPRIATIONS

At one time or another, almost everyone has had the frustrating experience of not being able to draw from supply some item that he thought necessary to have immediately; the usual reason given being, "We don't have any money left." It takes only a short time to realize that the Navy does not operate with unlimited funds. This section and the following section, titled "Allotments," are presented to further an understanding of the system whereby funds are made available at the user activity level for operating expenses.

753

The main money pool of the government is the General Fund of the Treasury. Funds come into the General Fund from such sources as income taxes, excise taxes, import-export taxes, etc. The only way for money to be expended from the General Fund is by congressional action, which has to be approved by the President. A bill passed by Congress which includes the expenditure of funds from the General Fund is called an appropriation.

An estimate of the amount of money required for the operation of the Defense Department during a given fiscal year is prepared by Department of Defense fiscal experts well in advance of the beginning of the fiscal year. The Congress studies the proposed budget in the light of world affairs, the current domestic economy, and such other considerations as they see fit, then acts upon it. They may increase the amount requested, decrease it, or pass it as is. After presidential action is completed, the money is made available to the Department of Defense to be spent during a specified year. This is known as an "annual" or "1-year" appropriation.

Congress and the President may also approved "no-year" appropriations for special projects such as large construction over an unspecified length of time. Another form of appropriation is the "multiple-year" appropriation for projects which will be completed in a predictable length of time. An example of this type of appropriation might be the money appropriated to cover the expenses of the NROTC college programs for the next 4 years.

The appropriation by which the technician is most affected is the current year appropriation. After the appropriation or expenditure authorization is received in the Department of Defense, it is prorated among the services as a percentage of their previously submitted budget estimates. The Navy's share is prorated among the various bureaus and commands in essentially the same manner; that is, as a percentage of their estimated requirements for the coming fiscal year. The money to be spent for naval aviation is made available to the Naval Air Systems Command. Here, part of the money is allocated to ASO for the purchase of aircraft spare parts in quantities which past usage data has indicated will probably be sufficient for the coming year. These spare parts are furnished to the operating activities at no cost, since their usage has been anticipated and the items paid for in advance. The account from which money was spent to buy these items is known as the Appropriation Purchase Account. Material received in the user activities from this account is known as APA material.

Another part of the Naval Air Systems Command funds is made available to the operating activities in the form of allotments.

ALLOTMENTS

Allotments concerning naval aviation are authorizations by the Naval Air Systems Command to the user activities to spend a certain amount of money during a given length of time for specific purposes. User activities are shore commands which operate aircraft, and the major air type commanders. Major air type commanders are Commander, Naval Air Force, Atlantic (ComNavAirLant); Commander, Naval Air Force, Pacific (ComNavAirPac); Chief of Naval Air Training (CNATra); and Chief of Naval Air Reserve Training (CNAResTra). Operating funds for squadrons and units are apportioned to them by their type commander as an Operating Target (OPTAR). Routine nonaviation expenses for operating squadrons and units are absorbed by the ship or station to which assigned.

There are three types of allotments—operation and maintenance, operation and line maintenance of aircraft, and aviation fleet maintenance. These three allotments are of particular concern to the technician and are discussed further.

Operation and Maintenance Allotment

Funds in this allotment are made available to commanders of the shore establishment to pay their operating expenses, exclusive of aircraft operating expenses. This money is used to pay civilian labor, buy office supplies, and to pay for all other upkeep and housekeeping supplies. Squadrons aboard the station have no allotment of this type and are dependent on the station for their support. A segment of the station's allotment is allocated to the squadrons for their nonaviation routine expenses. Funds from this source are generally scarce, but it is possible by careful management to make them last through the specified spending period. Shore commanders, in some cases, may elect to provide basic supplies in limited amounts to the tenant activities without providing any funds which the squadron or unit can spend as needed.

Operation and Line Maintenance of Aircraft Allotment

Major air type commanders and shore commands which operate aircraft are furnished this allotment by the Naval Air Systems Command. The OPTAR provided to fleet squadrons and units by their type commanders is usually a monthly segment of these funds. Unused funds revert to the control of the type commander as each new OPTAR is authorized. Type commanders provide OPTAR's to all squadrons and units under their operation control, whether or not the user activity is based ashore. Shore station commanders have no responsibility for providing money for the operation and line maintenance of aircraft of tenant fleet activities.

Funds allotted for the operation and line maintenance of aircraft may be used to buy any type material as long as the material is used for the purpose of the allotment. By far the greatest expenditures against this account are for fuel and oil. Other materials that may be purchased with this allotment include rags, aircraft paints, preservatives, crewmen's flight clothing, or anything else that is consumable due to its use on or about the aircraft.

Aviation Fleet Maintenance Allotment

Air type commands are furnished this allotment by the Naval Air Systems Command, then the Air type command will furnish funds to ships by OPTAR, and fleet support stations are funded by suballotment. These funds are provided to finance the cost of Intermediate and Organizational levels of maintenance. These costs include the following:

1. Technical repair parts, common hardware, lubricants, cleaning agents, cutting compounds, metals, etc., incorporated into or expended in the performance of aviation maintenance of aircraft, aircraft engines, aeronautical components and subassemblies, and Navy maintenance of the Naval Air Systems Command authorized maintenance support equipment.
2. Fuels and lubricants consumed by aircraft engines in the performance of complete section repair.
3. Preexpended, consumable maintenance material.
4. Replacement of consumable/expendable allowance list items (Material Accountability and Recoverability Codes "B" and "C").

DISTRIBUTION SYSTEM

The aviation supply distribution system consists of reserve stock points, primary stock points, secondary stock points, and satellites. These are discussed briefly in the following paragraphs.

1. RESERVE STOCK POINTS carry reserve and backup stock for the aviation supply system. The range and quantity of stock are determined by the Aviation Supply Office. Reserve stock points provide storage facilities for bulk material.
2. PRIMARY STOCK POINTS carry stock for their own consumption. They may be designated as support activities for secondary stock points, for fleet units, and/or yard and district craft in the area.
3. SECONDARY STOCK POINTS carry stock for their own consumption as well as stock for aircraft and assigned yard and district craft.
4. SATELLITES are aviation activities which are dependent for support on a primary or secondary stock point. Satellites are usually minor activities and normally receive their supply support on a retail issue outlet basis.

As far as the consumers are concerned, they may be assigned to any of the primary, secondary, or satellite stock points for supply support. The same basic principles will affect your supply support. (Hereafter in this training course, they are referred to as field supply points.)

MATERIAL IDENTIFICATION

As aviation maintenance personnel, we will be working closely with the aviation storekeepers in keeping aircraft in an "up" status. In order to obtain replacement parts as rapidly as possible, we must know how to determine the source of supply of different items. For example, we may waste many hours trying to find out that the item is to be manufactured within our own activity. Also, it is important to know the correct stock number and cognizance symbols used to requisition items from supply.

The cataloging system developed by the Department of Defense is such that it identifies with one name and stock number any item of supply that is carried in any or all government agencies. In the procurement of material it is normally necessary to identify your material requirement in the medium understandable to the supply system.

FEDERAL STOCK NUMBERS

Prior to 1952 each of the services had its own numbering system for identifying, cataloging, stocking, and issuing items of military supply. It was not unheard of that one service would be negotiating on the open market for an item that was held in surplus by another service under its own stock number. This confusion resulted in the passage in 1952 of the Defense Cataloging Standardization Act.

The implementation of this Act has resulted in a reduction of item duplication between the services by providing for one Federal Stock Number (FSN) for each item, regardless of the use of the item or the using activity.

Coded Federal Stock Number

The federal stock number consists of an 11-digit number. The Aviation Supply Office uses federal stock numbers with prefixes composed one, two, or three symbols, and suffixes composed of four characters which may be all letters or a combination of letters and numbers. When the prefixes and suffixes are used, the federal stock number becomes a coded federal stock number. A coded federal stock number and its breakdown is shown in figure 4-1.

If a 1-symbol prefix is used, it designates the command or office having control or cognizance of a particular item. Listed below are some of the more common cognizance symbols, together with the type material controlled and the name of the cognizant command or office.

SYMBOL	COGNIZANT ACTIVITY	MATERIAL CONTROLLED
2R	Aviation Supply Office	Aeronautical material
2V	Naval Air Systems Command	Major aeronautical equipment
1N	Electronics Supply Office	Electronic assemblies and repair parts
1W	Fuel Supply Office	Fuels, lubes, and gases
1I	Navy Supply Depot, Philadelphia	Forms
0I	Navy Supply Depot, Philadelphia	Publications

Many variations of coded stock numbers will be encountered in field maintenance work. These variations indicate material management responsibilities for the item; flag certain items as recoverable, consumable, high value, etc.; and identify the condition of the material if it is not ready for issue. Some of the more common codes that a technician is likely to encounter include the following:

RH—a recoverable aeronautical component of high value.

2RHF—a recoverable aeronautical component of high value that is not ready for issue.

Figure 4-1.—Breakdown of Coded Federal Stock Number.

Because the variety of codes is so extensive and the trend to single service management of items has caused so many changes in recent years, a list of codes that might be prefixed or suffixed to a stock number would not be appropriate for this course. The primary things to keep in mind are that the basic stock number, consisting of three groups of numerals, identifies the item from a technical point of view and that the other codes identify material management characteristics.

With the advent of the single manager concept many items formally carried in the individual Navy Stock Lists are cataloged in the Federal Supply Catalog For General Supplies. The complete catalog consists of many sections and is arranged by federal supply classification class.

MATERIAL IDENTIFICATION AIDS

There may be times when a part or some technical material is needed and the stock number is unknown. At other times some material may be on hand and its identity is not positively known. A knowledge of the several methods by which material may be identified is very helpful in speeding the completion of a maintenance task. There are many ways in which material may be identified. Certain data may be available which does not identify an item but may lead to positive identification. An aircraft part has a part number. The part number may be looked up in the IPB and identified by nomenclature and often by the stock number. If the stock number is not furnished in the IPB, it may be found by referring to the Cross-Reference Section C0006 of the Navy Stock List of ASO.

Some equipments have attached nameplates which provide such information as the manufacturer's name, make or model number, serial number, size, voltage, phase, etc. Identification data taken from the nameplate of the old part can be very helpful in procuring a replacement.

When only the description of the item is known, the best source for identification is the descriptive sections of the various Navy Stock Lists.

Various publications used in identifying material are described in the following paragraphs.

NAVSUP PUBLICATION 2002, SECTION VIII, PARTS C and D, contains a complete numerical listing of all available naval aeronautic publications distributed by Naval Air Systems Command. This stock list is supplemented by and should be used in conjunction with NavAir 00-500A, Equipment Applicability List, and NavAir 00-500B, Aircraft Application List. These lists are handy references to publications that should assist you in the identification of material.

ILLUSTRATED PARTS BREAKDOWN (IPB) lists are probably the most important tool for the identification of aeronautical material. As a senior Petty Officer, you are undoubtedly familiar with them. However, due to the importance attached to them as a material identification source, they are discussed briefly in the following paragraphs.

IBP's are compiled by the manufacturer for each aircraft model in naval use. IPB's, as discussed here, encompass IPB's for aircraft, IPB's for aircraft engines, and IPB's for individual accessories and equipments.

Although slight variations in format exist among the various IPB's, each normally includes the following major sections:

I. TABLE OF CONTENTS—This section shows the breakdown of the catalog into sections and furnishes a cross-reference between the various assemblies and figures where they are illustrated. The section also cross-references assemblies and pages where they are broken down into subassemblies and parts.

II. INTRODUCTION—This section includes general information and instructions for using the publication. Because variations between IPB's do exist this section should be referred to prior to using an IPB with which you are not thoroughly familiar.

III. GROUP ASSEMBLY PARTS LIST—This section is the main text of the publication. It consists of a series of illustrations and parts lists in which all parts of the aircraft/engine/equipment are shown in assembly breakdown order. The illustrations and parts lists are keyed to each other by means of figure and index numbers. Each assembly included in the parts lists is followed immediately by its component parts properly indented to show their relationship to the assembly. The group assembly parts list is subdivided into groups such as wing group, tail group, and fuselage.

IV. NUMERICAL INDEX—This section lists all parts in alphanumerical order, and each part is cross-referenced to the figure and index number where it is illustrated. This list also shows the official source code of each part listed in the applicable IPB.

Source codes are codes which indicate to a consumer a source for a part required in the maintenance or repair of an aeronautical article. They are provided in six series—P, M, A, N, X, and U.

The REFERENCE DESIGNATOR INDEX, normally the last section of the IPB, is a listing of reference designators (C104, R603, K202, etc.) used on the electrical and electronic wiring diagrams. The reference designator index will aid in the location of parts where only the reference designation number is known.

Source code P series parts are parts of supply system stock which are purchased.

Source code M series applies to parts which are not purchased but are capable of being manufactured at Navy fleet or overhaul activities (MF, MO, or MOA).

Source code A series applies to assemblies which are not purchased.

Source code N applies to nonstock items which are purchased on demand.

Source code X applies to main structural members or similar parts which, if required, would suggest extensive repair. The need for a part or parts coded X normally results in a recommendation for complete overhaul or retirement of the equipment from service.

Source code X1 applies to items for which purchase of the next larger assembly, source coded in the P series, is justified.

Source code X2 is applied to items which are not purchased for stock, but may be acquired for use through salvage or one-time purchase. Activities requiring such items should attempt to obtain them from salvage; if not obtainable from salvage or readily manufactured, such items may then be requisitioned through normal supply channels with supporting justification. Repeated requisitions could justify a change to the P series code.

Source code U applies to parts which are not of supply or maintenance significance, such as installation drawings, diagrams, instruction sheets, etc.

Within each of the source code series listed above there are one or more subcodes identified by a letter or number appended to the basic code letter. These subcodes provide detailed information concerning the procurement or manufacture of various parts within the scope of the particular code series. The introduction section of the applicable IPB provides a ready reference for each of the codes and subcodes as required.

Aeronautical Allowance Lists

Aeronautical allowance lists as used in this course include NavAir Allowance Lists, NavAir Initial Outfitting Lists, and NavAir Tables of Basic Allowance.

Aeronautical allowance lists are lists of equipment and material, known or estimated to be required, to place and maintain aeronautical activities in a material readiness condition. These lists contain substantially all items used with sufficient frequency to justify their issuance to all activities maintaining aircraft or equipment for which the lists are designed. They also contain information concerning stock number, nomenclature, interchangeability, and supersedures. These publications are further defined in subsequent paragraphs. Keep in mind that allowance lists normally contain support equipment allowed to maintenance personnel consistent with their assigned level of maintenance. Initial outfitting lists contain material of a spare parts nature required for maintenance of aircraft/equipments. Materials listed in the initial outfitting lists normally are held in supply stocks and under most conditions are not authorized shop spares.

Allowance lists indicate the range and quantities of support equipment considered necessary for maintenance support of assigned and/or supported aircraft. Generally, these items are in-use items required for daily or continual use, such as handtools and avionics test equipment.

Initial outfitting lists (IOL's) are publications which indicate the range and quantities of maintenance spare parts considered necessary to support various aeronautical articles. This material is provided to vessels or activities and is firm only at the time of initial outfitting. Increases and decreases in both range and/or quantities of material are based upon the experience (demand history) of each activity concerned. Each series list is designed to support an aircraft, electronic equipment, or some other aeronautical article. The allowances of material are established for various articles for a 90-day period. All items capable of replacement by a maintenance activity are not listed, but rather, only those that are expected to be used at least once in 9 months.

Publications listing equipment and material required for performance of specific functions are known as Tables of Basic Allowance. They contain both shop equipment and common supporting spare parts. They cover allowances

of tools and equipment required for use by such activities as Fleet Marine Force squadrons and guided missile activities.

Initial Outfitting Lists and Allowance Lists are identified by the publication number NavAir 00-35Q series, while Tables of Basic Allowance are identified by the publication number NavAir 00-35T series. Those allowance lists of primary interest are listed in the following paragraphs:

Section "A" Initial Outfitting List (NavAir 00-35QA-1)—Lists standard aeronautical and Navy stock account material common to the designated aircraft classes.

Section "B" Initial Outfitting List (NavAir 00-35QB)—Series lists peculiar maintenance parts (airframe, engine, accessories) required for support of specific aircraft models. (Includes lists for certain target aircraft and guided missiles.)

Section "BR" Initial Outfitting List (NavAir 00-35QBR)—Series lists peculiar maintenance parts (airframe, engine, accessories, electronics) required for support of concerned target aircraft model, drone helicopter, or guided missile. (Prepared in lieu of separate Section "B" for airframe, engine, accessories, and Section "R" lists for electronic parts due to limited installation of electronic equipment.)

Section "G" Allowance List (NavAir 00-35QG)—Series lists general maintenance support equipment and handtools required for intermediate and organizational levels of maintenance support of aircraft.

Section "R" Initial Outfitting List (NavAir 00-35QR+4)—Lists general aeronautical electronics material common to and required for maintenance of avionics equipment and systems.

Section "R" Allowance List (NavAir 00-35QR-5)—Lists avionics support equipments required for maintenance of installed avionics equipment and systems. A confidential supplement to NavAir 00-35QR-5 is issued as a separate publication.

Section "R" Initial Outfitting List (NavAir 00-35QR-5A)—List peculiar parts required for maintenance of electronic test equipments authorized in NavAir 00-35QR-5.

Section "R" Initial Outfitting List (NavAir 00-35QR-6)—Lists aeronautical electronic accessories common to designated aircraft classes.

Section "R" Initial Outfitting List (NavAir 00-35QR-7)—Lists electron tubes required in the maintenance of aeronautical equipment utilizing such tubes.

Section "R" Initial Outfitting List (NavAir 00-35QR-30)—Series lists peculiar parts, spare components, assemblies, and subassemblies required for maintenance of appropriate aeronautical electronic equipments.

Section "T" Allowance List (NavAir 00-35QT)—Series lists special maintenance support equipment required for intermediate and organizational levels of maintenance of airframes, powerplants, accessories, avionics equipment, and/or aircraft model to which the list applies.

Section "X" Initial Outfitting Allowance List (NavAir 00-35QX-30)—Series lists peculiar parts, spare components, assemblies, and subassemblies required for maintenance of the armament, fire control, instrument, or electrical system to which the list applies.

Section "Z" Initial Outfitting List (NavAir 00-35QZ)—Series lists peculiar parts for electric powerplants, special and general aircraft, and guided missile support equipment.

Tables of Basic Allowances (NavAir 00-35T)—Series (T-37-1, T-37-2, T-37A, T-38, T-39, T-40, and T-41) lists equipment and material required by activities to which the list applies for performance of assigned mission. Lists presently in effect relate to the following activities:

T-37-1, T-37-2..	Fleet Marine Force Aviation Units.
T-37A	Fleet Marine Force Aviation Units (Supply Officers' material and equipment).
T-38.....	Target Pilotless Aircraft Activities; Drone Aircraft Catapult Control Craft; Navy Tactical Control Squadrons.
T-39.....	Regulus Guided Missile Activities.
T-40.....	Air-Launched Guided Missile Activities.
T-41.....	DASH Weapons System Operational and Maintenance Activities.

Stock Catalogs

Stock catalogs provide information necessary to procure items for operation and maintenance

of activities afloat and ashore. The stock catalogs commonly used by aviation maintenance personnel are the Federal Supply Catalog for General Supplies and the Navy Stock List of ASO for aeronautical material.

The Navy Stock List of ASO is divided into four parts, each consisting of several volumes. Many of these stock list sections are designed for supply management purposes and have very little significance to maintenance personnel. The sections normally utilized by maintenance personnel include the following:

1. Sections C0006 and C0009 are cross-reference sections. The section C0006 is used to cross-reference a manufacturer's part number to a federal stock number. The section C0009 is used to cross-reference a federal stock number to a manufacturer's part number. These are multiple volume sections and are not normally available in individual shops, but may be available in a centralized area for use by several shops. These sections are published annually with cumulative supplements being issued monthly.

2. Parts list sections provide supply data to supplement information contained in the Illustrated Parts Breakdown. These sections contain valuable information relative to application and interchangeability. Parts list sections are set up by TSMC. Each section contains an application checkoff list, a listing of repairable assemblies, and a listing of supporting spare parts.

3. Descriptive sections are used when only the item nomenclature and physical characteristics are known. Illustrations are provided to aid in the identification of items that cannot be defined by words. The descriptive sections are established by federal supply classification class.

MATERIAL REQUISITIONING

Maintenance personnel are apt to encounter a variety of local requisitioning channels; all designed to present a demand for an item to the supporting supply department. Assigned levels of maintenance, geographical location of shops relative to supply facilities, and mission of activities requiring support all influence the local requisitioning channels. Local instructions normally promulgate detailed procedures for submitting your demand to the appropriate supply point.

SUPPLY ACTIVITY

The mission of the supply activity is to support the operational and maintenance efforts of the activity/ship. Stocks of aviation oriented material carried are tailored and replenished to this end. Positioning, replenishment, and control of stocks of material in maintenance areas are carried out as a result of joint decisions by the Supply and Maintenance Officers concerned. They determine the range, depth, and related procedures. The Navy Maintenance and Material Management System (Aviation) requires that the cost of material used in maintenance be determined and accumulated in such manner and detail that weapons system costing can be measured. Usage is finely defined as to stock number, within component, within equipment/weapon/aircraft, in a particular squadron, located in a specific operational area, at a definite point in time. These data are used as an inventory management tool to determine geographic and strategic distribution of stock of material. In addition, the data will be invaluable in establishing the material portions of work standards in maintenance.

Supply Support Center

Maintenance organizations have one single point of contact with the supporting supply activity. This single supply contact point is the Supply Support Center (SSC) which responds to all material requirements of the maintenance organizations. The SSC is an internal organization of the local supply activity. It is made up of three sections—the Supply Response Section (SRS), the Component Control Section, (CCS) and the Supply Screening Section (SSS).

Supply support is available consistent with the operating hours of the maintenance activities supported. If maintenance is being performed 24 hours a day, then supply support is available 24 hours a day.

The supply support center maintains rotatable pool material which consists of repairable ready-for-issue items reserved primarily to satisfy the requirements of Organizational level maintenance. Items maintained in the pool are capable of being repaired by the local Intermediate maintenance activity, have application relationship to weapon systems supported by local Intermediate maintenance activities, and have an average Organizational maintenance level removal rate of at least one per month.

Defective components are turned in to Intermediate level maintenance for repair. The defective components repaired to an RFI condition are then returned to the rotatable pool to replace the components previously issued.

Low value, fast moving consumable items are preexpended from supply. Such materials are located in the maintenance area. The establishment, maintenance, and replenishment of preexpended bins are the responsibility of the supply organization.

SUPPLY RESPONSE SECTION.—The Supply Response Section (SRS) is responsible for preparing all necessary requisitions (DD Form 1348) and related documents required to obtain material for local maintenance use in direct support of weapon system maintenance. The maintenance organization verbally notifies the supply organization of the need for such material. When material is available locally, the time frame for processing and delivery is as follows:

Priority	Process/Delivery Time
1-3	1 hour
4-8	2 hours
9-20	24 hours

Otherwise, the time frames as noted in table 4-1 will apply.

The SRS is responsible for receipt, storage, and issuance of all ready-for-issue pool components. It is responsible for physical delivery of RFI material to maintenance organizations, and the pickup of defective components from the Organizational maintenance activity and subsequent delivery to the Intermediate maintenance activity. Actual maintenance personnel are not involved in the physical movement of material between organizations.

This section also performs technical research in regard to completion of requisition documents as well as determining the status of outstanding requisitions and relaying this status to the customer upon request.

COMPONENT CONTROL SECTION.—The Component Control Section (CCS) accounts for all components being processed in the Intermediate maintenance activities. This section also maintains records on the status of all rotatable pool components.

SUPPLY SCREENING SECTION.—The Supply Screening Section (SSS) is responsible for initiating disposition action on components that cannot be repaired by the local Intermediate maintenance activity. Using listings and directives from inventory managers, screening personnel determine disposition of components in question, including prospective consignee and packaging and preservation requirement prior to movement of material.

Table 4-1.—Processing time frames.

Issue group	Issue priority designator range	Supply source processing	CONUS on station time	Overseas on station time
1	1-3	24 hours 24-hour day 7-day workweek	120 hours	168 hours
2	4-8	72 hours 24-hour week 7-day workweek	8 days	15 days
3	9-15	10 days 5-day workweek 8-hour day	20 days	45 days
4	16-20	12 days 8-hour day 5-day workweek	50 days	60 days

761

MATERIAL CONTROL OFFICER

The Material Control Officer in a maintenance activity is an assistant to the Maintenance/Material Control Officer, and as such provides support and services to the production divisions. Material control exists for the primary purpose of insuring that maintenance requirements for parts and materials are made known to the supply organization in a timely manner in order to prevent work stoppages and grounding aircraft. Material control insures that parts and materials made available to maintenance are systematically utilized and not allowed to accumulate or to become depleted. It serves as the single point of contact within the maintenance organization for the conduct of business with the supply organization.

Material Control provides material support to their cognizant organization by accomplishing the following general functions:

1. Pass all requirements for material required for direct support of weapon system maintenance to the SSC. A material control register is maintained for these items.
2. Prepare documents for materials required for indirect support of weapon system maintenance. Examples of materials for which documents are to be prepared are aviation fuels and lube oils, rags, and flight jackets. A separate requisition record log is maintained for these items.
3. Maintain liaison with the supporting SSC on maintenance material matters to insure that material needs of the organization are satisfied.
4. Establish delivery points for all material and insure that material received is expeditiously routed to the applicable work center.
5. Furnish technical advice and information to the supply activity on the identity and quantity of supplies, spare parts, and materials required for maintenance actions.
6. Establish procedures to insure the periodic inventory of tools and the adequate accountability of material and equipment on custody to the cognizant organization.
7. Initiate surveys in the event of loss, damage, or destruction of accountable material.
8. Keep maintenance control advised of the overall supply situation as it affects the activity.
9. Perform cost and allotment record accounting, charting, and budgeting of cost applicable to the cognizant organization.
10. Monitor the operation of toolrooms and maintain support equipment allowance lists.
11. Maintain inventory control of authorized allowances of material.

The material control is responsible for the coordination of material ordering, receipt, and delivery. This is done in such a manner as to insure that the correct material is ordered and that it reaches the work center within the specified time frame.

The foregoing functions of the material control division apply to both Organizational and Intermediate level activities. Some of the functions which are applicable to one level only are listed in the following paragraphs.

Intermediate Level

An Administrative Screening Unit has been established in Material Control of Intermediate maintenance activities. This screening unit does the following:

1. Positively identifies material and determines if it is within the repair capability of the Intermediate Maintenance Activity (IMA).
2. Insures that all required documentation is affixed to the component (i. e., logs, records, MAF, etc.).
3. Notifies maintenance control of the receipt of defective components for scheduling into the IMA.
4. Transfers the defective components to the appropriate work center when directed by maintenance control.

All components received in the IMA material control receive screening to determine if the item is within the check, test, or repair capability of the IMA. As a result of this screening, components requiring maintenance within the IMA capability are reported to maintenance control as ready for induction. Items beyond IMA capabilities are returned to the Supply Support Center with appropriate recommendations for disposition. When work on components in the IMA has been completed, the components, together with required records, are returned to material control for appropriate routing.

Organizational Level

In addition to the general functions, material control in Organizational level activities is responsible for the following:

1. Verification of NORS (Not Operationally Ready Supply) requisitions and maintain current NORS status records.

2. Inventory of aircraft upon receipt and transfer and maintenance of inventory records.

When removed components are generated as a result of the maintenance effort, material control insures that the SSC is notified to make a pickup. These components must be accompanied by record cards and logs, when applicable, plus the number two, three, and four copy of the MAF.

Material Control Register

The Material Control Register is used by Intermediate and Organizational level activities to record all materials requested from the supply support center in direct support of weapon system maintenance. Space is provided to record essential information considered necessary to monitor OPTAR funds. This information includes part number, priority, quantity, price, date, and time ordered, and date and time received. Maintenance control uses the time ordered and time received to help determine NORS time used in fulfilling readiness reporting requirements.

When a defective repairable item is turned in, the following forms are required: copies two, three, and four of the multicopy MAF and the Accessory and Component Service Record (NavWeps Form 13090/29), when applicable. The supply department uses copy two of the MAF for bookkeeping purposes. Copies three and four of the MAF accompany the item to the IMA. When repair is completed by the IMA, copy four of the MAF is attached to the RFI item and the item is returned to the supply system.

If material being turned in is no longer required and is RFI, a Single Line Item Release/Receipt Document (DD 1348-1) is submitted with the item. RFI means ready for issue in all respects—preservation still intact and item in original or reusable container with seals unbroken.

MILSTRIP

The Military Standard Requisitioning and Issue Procedure (MILSTRIP) and Uniform Material Issue Priority System were developed by the Department of Defense to provide a common supply language and more effective supply system operations within the military establishment. This system standardizes forms, formats, codes, procedures, and the priority system.

MILSTRIP employs two forms for the requisitioning and issuing of material. The Single Line Item Requisition Document (Form DD 1348) is the basic request document submitted to the applicable supply echelon for material requirements. The issue document is the Single Line Item Release/Receipt Document (Form DD 1348-1). Form DD 1348-1 is also used to return RFI material to the supply system. These forms will be prepared by the Supply Response Section of supply for all material requested in direct support of weapon system maintenance and by the material control for material requested in indirect support of weapon system maintenance.

Under the MILSTRIP priority system there is no decision to be made in assigning priorities. The urgency of need combined with the unit's military importance when applied to the priority number chart (table 4-2) indicate the proper priority number and no deviation is allowed.

There are two allowable exceptions to the force/activity designator governed priority number system.

Priority 3 will be used by all activities for *Medical or Disaster supplies.*

Priority 6 will be used by all activities for individual and organization clothing required to fill a minimum of essential clothing in the event an individual is without the clothing required.

Every activity is assigned 1 of 5 force/activity designations according to their military importance. These designators are as follows:

I - COMBAT—The highest order of military importance. This designator is not used in peacetime unless approved by the President or the Joint Chiefs of Staff.

II - POSITIONED—U. S. Forces positioned and maintained in a state of readiness for immediate combat or direct combat support.

III - READY—U. S. Forces maintained in a state of readiness to deploy for combat.

IV - RESERVE AND SUPPORT—U. S. active and selected reserve forces planned for employment in support of approved joint war plans. This category includes training units and units in training for scheduled deployment.

V - OTHERS—All units not otherwise assigned.

Force/activity designators are assigned by the Secretary of the Navy, the Chief of Naval Operations, and Commanders in Chief of Fleets. Authority to make assignments may be delegated

Table 4-2. —Priority number chart.

Designator	A Unable to perform	B Impairs capability	C Other than routine	D Routine
I Combat	1	4	11	16
II Positioned	2	5	12	17
III Ready	3	6	13	18
IV Reserve and support	7	9	14	19
V Others	8	10	15	20

to Fleet Commanders with the exception of I - COMBAT.

The urgency of need for an aircraft spare part or aeronautical material may be determined in accordance with the following designators:

A - Material and equipment for immediate installation or use to effect emergency repairs or replacement for an aircraft mechanically incapable of flight, or an aircraft incapable of performing its primary mission.

B - Material required to effect emergency replacement or repairs without which the operational capability of the activity will be impaired and decrease effectiveness and efficiency in accomplishing assigned operational missions and tasks will result.

Material required to effect emergency replacement or repairs without which the activity can operate only temporarily as an effective unit in performing its assigned operational mission and tasks. This includes material required for aircraft overhaul work stoppage.

C - Material required for emergency repairs or replacement of specific units of inoperative equipment or systems not essential to the operational effectiveness or safety of the force/activity.

Material required for scheduled deployment.

D - Material required in preparation for operational readiness.

Material required for scheduled maintenance of a specific aircraft or system.

Material required for initial outfitting and filling of allowances.

All stock replenishment actions other than previously prescribed.

If a squadron or unit has been assigned force/activity designator III and a branch supervisor determines that a part of some material is needed which if not received will impair the capability of the aircraft to perform its assigned mission, then the priority assigned must be number 6. The only other priorities available to force/activity designated III units or squadrons are 3, 13, and 18.

PARTS KITS

Parts kits contain supporting items and material for the maintenance, repair, and rework of selected aeronautical repairable type items and will be procured, stocked, requisitioned, accounted for, and used on a kit basis as one line item.

A parts kit consists of a group of maintenance or overhaul parts that are bought, packaged, and stocklisted as a single item regardless of classification that may be included therein. Normally, these parts have either a very low unit cost or have a high replacement rate in overhaul or repair of the next higher

assembly. Depending on the complexity of the end item, there can be one or more kits needed for its repair. Parts kits are designed to serve three separate requirements as described in the following paragraphs.

C KIT (CURE-DATED OR SOFT GOODS). This kit provides cure-dated items such as diaphragms, packings, and O-rings. The C kit may also contain soft goods not subjected to age control such as gaskets and seals, plus metallic items such as screws, nuts, and washers required to be removed when cure-dated or soft goods type materials are replaced. Any metallic item placed in the C kit is not duplicated in the D kit. When mixed categories or cure-dated parts are packaged in a single container, the control or cure-date of the package must be that of the oldest cure-dated part contained therein. If cure-dated kits become overaged due to the expiration of the storage limitations, the kit must be administratively disposed of as excess material.

D KIT (OVERHAUL). This kit provides hard good spare parts required for overhaul of equipment by depot level maintenance. This kit does not contain cure-dated parts.

F KIT (FIELD). This kit provides those items that are required to be replaced at intermediate and organizational maintenance levels. These parts are normally items not requiring special tools or equipment. This kit does not contain cure-dated parts.

Part numbers for applicable parts kits for intermediate and organizational levels of maintenance are listed in the Illustrated Parts Breakdown and the Maintenance Instructions Manual. Components of kits are additionally identified in the Illustrated Parts Breakdown by a footnote and a symbol appearing to the right in the part number column and indicating which items are furnished in the kit. The Maintenance Instructions Manual utilizes a symbol keyed to the illustration to indicate parts furnished in the kit.

Presence of a new part in an applicable parts kit eliminates the necessity of cleaning, inspection, or rework of the equivalent part removed from the assembly being repaired. Removed parts in this category must be administratively condemned. Removed parts not supplied in applicable kits must be handled in accordance with instructions contained in the Maintenance Instructions Manual.

Detailed instructions on parts kits are contained in BuWeps Instruction 4423. 2.

PREEXPENDED BINS

A preexpended bin is one which contains low cost, high usage items which have already been charged to final expenditure. Many items of small dollar value are used repetitively in the aircraft maintenance program. The accepted practice is to stock these repetitively used items in the immediate maintenance area in a semi-controlled preexpended bin. Preexpended bins are normally established by the supply department in consort with the maintenance activity and are labeled, stocked, and replenished by the supply department. The normal responsibilities of maintenance personnel in this are:

1. Recommending items to be stocked.
2. Supervising the use of the bins to prevent waste, pilferage, and deterioration of the contents to a scrap heap.
3. Insuring that preexpended bins are separate and distinct from the normal "salvage" boxes located in most shops.

Preexpended bins provide repetitively used items to maintenance personnel with the minimum of effort. The material is immediately available to all shop personnel. The bins also provide the supply department with a constant and realistic demand history.

Nonstandard and/or Navy manufactured items may at times be required. These are normally obtained through the normal supply channels as outlined in local directives.

Manufactured items are those items which are source coded in the M series in applicable illustrated parts breakdown lists. Request documents submitted for manufactured items should contain additional reference data such as, part number, drawing number, and publication reference, or any other information which would be advantageous in the acquisition of the material.

Nonstandard material (material requiring open purchase) may not be procured when standard stock items are available except when the nonstandard material is considered to be indispensable. When the procurement of nonstandard material is considered essential, the originating request document must contain the following information:

1. A certification that no standard stock material is suitable.
2. A justification for the procurement of the nonstandard material.

765

ROTATABLE POOLS

Rotatable pools consist of a range of selected components maintained by a specific maintenance activity, on custody from the supporting supply department. The items generally carried in the pool are those required to sustain operations where immediate availability is essential. Aircraft wheels, tires, avionics assemblies, propellers, and carburetors are examples of items that might be included in the pools. The range and quantity of items to be carried in the pool are subject to the recommendations of the maintenance activities. The supply department establishes the rotatable pool stock and prescribes detailed procedures for operation and control of the pool.

ACCOUNTING FOR MATERIAL IN USE

Accounting for material does not cease when it is withdrawn from the supply department. It is at this point that the accounting responsibility passes to the applicable maintenance personnel.

AIRCRAFT PARTS

Normally, the accounting for aircraft parts drawn to replace similar defective parts is satisfied when the part is installed on the aircraft. No further custodial records are required. The accounting for materials drawn for general maintenance is satisfied when the material is consumed in the authorized maintenance work. In these cases it is actually the removed defective material that requires additional action to insure its accountability from the time it is removed unitl it is returned to the supply department.

The degree of accountability required for aeronautical material may be ascertained by the material accountability recoverability codes (MARC). Material accountability recoverability codes are a part of the source, maintenance, and recoverability codes which are assigned provisioned items as required by current ASO and BuWeps/NavAir directives. The MARC's appear in the descriptive sections and parts lists sections of the ASO Navy Stock List, NavAir Allowance Lists, and may appear in such other publications as directed by NAVAIRSYSCOM. These codes aid personnel to determine the proper method of:

1. Requisitioning material.
2. Accounting for material while in use.
3. Turn-in or disposition of material.
4. Repair or overhaul of material.

The following list defines the various material accountability codes.

B - Exchange Consumables. Code B is applied to items which are consumable or expendable but normally require item-for-item exchange for replacement. Such items may contain precious metals, may be highly pilferable, or may be high cost items.

C - Consumables. Code C is applied to all other consumable or expendable items which do not require item-for-item exchange for replacement.

D - Equipage, Support Type. Code D is applied to end items of support equipment which are economical and practical to repair on a scheduled basis through a major rework activity. Code D items are maintained on a custodial basis and normally require item-for-item exchange for replacement.

E - Equipage, Locally Repairable, Support Type. Code E is applied to end items of support equipment which are to be repaired locally by the using or fleet support activity within their assigned maintenance responsibility. Code E items are maintained on a custody basis and normally require item-for-item exchange for replacement.

R - Equipage. Code R is applied to repairable (except end items of support equipment) items which are economical and practical to repair on a programed basis through a major rework activity. Code R items are maintained on a custody basis in some cases, depending upon the use of the item. These items normally require item-for-item exchange for replacement.

L - Equipage, Locally Repairable. Code L is applied to repairable (except end items of support equipment) items which are to be repaired locally by the using or fleet support activity within their assigned maintenance responsibility. Code L items are maintained on a custody basis in some cases, depending on the use of the item. They will normally require item-for-item exchange for replacement.

Some allowance lists may still be in use which utilize a different accountability code system than MARC. The following equivalents may apply, pending issuance of new publications

using the latest material accountability recoverability codes:

MARC	INTERIM	OLD
D	A	A
D	O	A
D	E	AX
R	R	X
B	D	NONE
C	C	C
E	NONE	NONE
L	NONE	NONE

As is apparent upon reviewing the material accountability recoverability codes, the disposition of defective material is largely dependent upon its potential repairability. Codes D, E, R, and L signify that the item is repairable and is required to be returned to the supply system even though it is not RFI. The need for the expeditious handling of prospective repairable material cannot be over-emphasized. The repair program is the prime source of supply for many critical high value items. Code C items are normally consumed or are not of a repairable nature and do not require turn-in if non-RFI.

An aeronautical material screening unit is established by all activities assigned the responsibility to perform intermediate level maintenance. The basic responsibility of the screening unit is to screen all defective aeronautical material generated on the station by tenant squadrons and station operating units prior to further processing of the material by the supply system or higher echelons of maintenance. The screening unit determines if such material is within the repair responsibility of local intermediate maintenance activities and, if so, initiates action to effect its local repair.

Normally, the following sequence of events should be followed in the repair of aeronautical material:

1. The using activity should repair the defective item without removal from the aircraft.
2. The using activity should remove the defective item from the aircraft, check, test, and repair it within their assigned responsibilities and replace it on the aircraft.
3. In the event the item requires repair and the time involved is excessive from the operational or readiness point of view, the using activity may draw a replacement item from supply. The defective item should be forwarded to the supporting intermediate maintenance activity's screening unit.
4. This screening unit determines if the item is within the repair responsibility of the intermediate maintenance activity, and, if so, the item is repaired and forwarded to supply as RFI. If not, the item is forwarded to supply as prospective repairable material.

The basic form used in the reporting of failures, deficiencies, or malfunction of aeronautical material is the Unsatisfactory Material Condition Report (UR), NavWeps 13070/5. It is designed so that certain copies may also be used for custodial purposes of the defective material including its return to the supply department.

AIRCRAFT MAINTENANCE SUPPORT EQUIPMENT

Developing and supervising proper procedures to insure the maintenance and accountability of aircraft maintenance support equipment (AMSE) is normally a prime administrative function of the senior technician. Unlike most aircraft parts, AMSE requires the maintenance of custodial records and periodic physical inventories throughout its in-use life.

Aircraft maintenance support equipment as discussed in this chapter applies to all accountable type support equipment listed in NavAir Allowance Lists, Sections "G," "O," "R5," "T," and "TBA's." Accountable AMSE items are those assigned material accountability recoverability codes "D" and "E." These items are assigned material control code X which appears as part of the federal stock number identification.

Because stocks of AMSE are so limited, issues are strictly controlled to insure proper program support. After initial outfitting, AMSE items are issued on an item-for-item exchange basis. When an AMSE item is lost, missing, or beyond economical repair, and replacement is required, approval of the replacement item is granted only when accompanied by a copy of the survey document. Aircraft maintenance support equipment is issued by the supply activity to the end user only upon approval by the following:

1. The cognizant type commander or his designated representative for fleet and training command activities.
2. The cognizant NavAirSysComRep for Naval Air Rework Facilities (NARF's) and shore activities.
3. ASO for special programs, bailment programs, military aid programs (MAP), etc.

Aircraft maintenance support equipment includes such items as test stands, lubricating guns, special wrenches, drills, compass testers, and voltmeters as listed in the Allowance Lists mentioned above. These equipments are made available as organizational property or custody/subcustody from supporting station/squadron/vessel dependent upon the characteristics of the equipment and the assigned maintenance, operational, and/or logistics responsibilities. Except for vessels, equipments required are authorized through the application of appropriate allowance lists as shown in enclosure (2) to BuWeps Instructions 04700. 3. This enclosure consists of an allowance list applicability chart (ALAC) for each activity of the naval shore establishment indicating the equipment by allowance list category authorized to specific activities. Actual equipment authorized for naval vessels may be determined from BuWeps Instruction 4423. 3 (Series).

Under the aircraft maintenance material readiness list (AMMRL) program all applicable intermediate and/or organizational maintenance support equipment listed in the various allowance lists are consolidated into one individual material readiness list (IMRL) for each aircraft maintenance activity. Each IMRL is approved by the cognizant fleet or training command and is used as the firm mandatory material readiness list of the activity to which the list applies.

All aircraft maintenance support equipment must receive continued accountability while in use. The activity having prime custody of the support equipment is considered to be the accountable activity. Equipment furnished as organizational property is accountable activity. Equipment furnished as organizational property is accounted for by the holder of such equipment. Equipment furnished or received on subcustody is accounted for by the supporting activity.

The department head is held responsible for the maintenance support equipment in his department. Senior Petty Officers normally are required to receipt on subcustody for all the AMSE in their shops. Periodic inventories are required to ascertain if material for which you are responsible is actually on hand. Material which cannot be accounted for must be surveyed.

An annual inventory of in-use aircraft maintenance support equipment is required to provide ASO and Naval Air Systems Command with an accurate assessment of the quantity and condition of this support equipment in the possession of custodians in order that sound decision can be made concerning the procurement of new and replacement equipment. Type commanders or the NavAirSysComRep forwards to all activities having reportable items of support equipment a deck of EAM cards and/or an EAM listing indicating those items of support equipment requiring inventory. Care should be taken to insure that items held or issued on a custody basis are reported only by the controlling custodian.

Transaction reporting of selected AMSE items is sometimes required. Type commanders or NavAirSysComRep selects the items of AMSE desired to be reported on a transaction basis and publish appropriate instructions for reporting. Upon receipt or transfer of an item of AMSE (subject to transaction reporting) on a permanent basis, or when the condition or status of equipment changes, activities are required to submit a transaction report.

HIGH VALUE ASSET CONTROL SYSTEM

The high value asset control system (HIVAC) is the result of SecNav Instruction P4440. 29 (Series). This instruction prescribes a Navy-wide high value item management program. The purpose of the program is to achieve inventory economies without impairing combat readiness. In the past the military services have been criticized for management deficiencies which led to accumulation of costly excess stocks.

The need for specialized, intensive management attention to a relatively small percentage of items can be better understood when considering the ever-increasing costs of weapon systems and the increase in the costs of the major supporting spares and components for these systems. These costs have had an impact on the national economy approaching that of military expenditures of World War II.

By using the best techniques in the management of high value items, which represents approximately 40 percent of the annual procurement dollar expenditure, inventories and procurement investments can be reduced considerably and still maintain an acceptable level of readiness.

High value items, as described in BuSandA Instruction 4440. 105 (Series), and identified by a specific material control (fraction) code on all supply documents as follows: Repairable items with a unit cost of $1, 000 or more

768

are assigned Material Code "G." Consumable items with a unit cost of $1,000 or more are assigned Material Code "J." There are control codes assigned to items other than those mentioned, but these two require worldwide movement accounting.

Although the technician is not directly involved in the program, he is involved at fleet level in that some of these items will be installed in aircraft or held in rotatable pools for which he may be required to assume responsibility. The major responsibility of fleet personnel is supply discipline, since supply discipline in the fleet is an especially critical aspect of the high value program. This is because of the greater difficulty of maintaining accountability under the pressure of operating conditions. Also, prompt action on the part of fleet personnel to expedite handling of high value items is essential to the program. For complete and detailed information concerning the HIVAC system, refer to the instruction previously mentioned in this section.

SURVEYING ACCOUNTABLE MATERIAL

When property must be reevaluated or expended from the records due to loss, damage, deterioration, or normal wear a survey must be made to obtain proper authority to write this material off the books. The survey request provides a record showing the cause, condition, responsibility, recommendation for disposition, and authority to expend material from the records. Think of a survey as being an administrative examination into the cause of material being lost to use. A survey may be either informal or formal, depending on the circumstances.

A formal survey is required for those classes of materials or articles so designated by the bureaus, commands, or offices concerned, or when specifically directed by the commanding officer. A formal survey is made by either a commissioned officer or a board of three officers. At least one of the board members must be a commissioned officer. The commanding officer appoints those who serve on the survey. Neither the commanding officer, the officer on whose records the material being surveyed is carried, nor the officer charged with the custody of the material being surveyed, may serve on a survey board.

An informal survey is made by the head of the department having custody of the material to be surveyed. Informal surveys are used in all cases when a formal survey is not required or directed by the commanding officer.

Preparation of Request for Survey

You will not have the responsibility of preparing final survey forms; however, as a first class or chief, you are apt to be required to provide your division officer with certain information when he is making a survey. Because of this, you should be familiar with the general procedures that are followed.

A request for survey may be originated by a department, division, or section head or a designated subordinate as prescribed by local regulations. Normally, requests for survey are originated in the department having custody of the material being surveyed. The initial survey request is made on a rough copy of S. and A. Form 154. A statement by the originator is placed on or attached to the request for survey relative to the condition of material; cause of condition surrounding the loss, damage, deterioration, or obsolescence of material; responsibility for cause or condition of material or reason why responsibility cannot be determined; and recommended disposition of material or action to be taken.

Upon receipt of the rough copy, the designated group or section prepares a sufficient number of smooth copies of the request for distribution in accordance with local regulations. The smooth survey request is filled out down to the caption Report. It is then forwarded to the commanding officer who will determine whether the survey will be formal or informal. If formal, the survey request is forwarded to the designated surveying officer(s); if informal, it is forwarded to the head of a department for survey action.

The statement by the originator as to cause, condition, etc., is attached to the smooth request for survey for evaluation by the surveying officer(s). After the survey has been completed by the head of a department or surveying officer(s), it is returned to the commanding officer for review and action. After approval by the commanding officer, the survey request is forwarded to the cognizant command for final review and approval when so required.

769 770

CHAPTER 5

AVIONICS MAINTENANCE SUPERVISION

The job of supervising the operation of a division or shop is a many sided task. Some of the techniques will have been learned through past experience. Others may be learned from self-study courses and technical publications. Still other techniques will have to be learned during the actual supervision of the division or shop. The purpose of this chapter is to acquaint the new supervisor with some of the more important aspects of shop supervision.

OBJECTIVES OF SUPERVISION

Briefly, the objectives of supervision are as follows:

1. To operate with maximum efficiency and safety.
2. To operate with minimum expense and waste.
3. To operate free from interruption and difficulty.

While these are the primary objectives of shop supervision, it is well for the man who may be assigned these duties to keep in mind the fact that his new assignment is important to him personnally, since it affords him in an excellent opportunity to gain practical experience toward future promotions.

OPERATION WITH MAXIMUM EFFICIENCY AND SAFETY

The operational efficiency of a shop is dependent to a large extent upon how conveniently the work spaces and equipment are arranged in the shop and upon the extent to which the shop, files, and equipment are maintained. Equipment in good working order, tools in good shape and of the proper type and quantity, and an up-to-date file of applicable publications are all important factors toward a smoothly running aircraft maintenance shop.

As some equipment becomes obsolete and new equipments and new models of equipment are phased into the shop inventory, the efficiency will increase to a certain extent, but may still be short of the full potential. Making a drastic rearrangement to improve the utilization of a single piece of equipment may not be economically feasible; however, a drastic change which results in improved utilization of several equipments may be worthwhile. The new shop supervisor will want to make an evaluation of the existing shop layout to assure himself that he has the most efficient arrangement possible.

The shop functions may be further smoothed by the judicious delegation of authority. The delegation of authority does not relieve the supervisor of the final responsibility for work accomplishment. It is primarily a means of relieving the supervisor of details. A supervisor who allows himself to become too involved with details loses his effectiveness as a supervisor.

A supervisor should know his men's limitations and capabilities in order to get the most work out of them. He should exploit the capabilities of his best men in a twofold manner. If at all possible he should assign a well-qualified man to do a certain job and add to the team other individuals who are less qualified but who are professionally ready for advanced on-the-job training.

The supervisor must anticipate the eventual loss of his most experienced workers through transfers, discharges, etc., and offset this by the establishment of an effective and continuing training program. In addition to raising the skill level of his division, the training program will insure that personnel, otherwise qualified, will be ready for the advancement in rating examinations.

A shop safety program must be organized and administered if the shop is to function efficiently. Current Navy directives and local policies are quite specific as to the establishment of safety training programs. A worker

is not much good to anyone if he is laid up in the sickbay.

The keeping of accurate and complete records is another factor in the efficient operation of a shop. The most efficient recordkeeper is one who has enough records without having his files bulging with useless and outdated material.

A knowledge of the principles of man-hour accounting is necessary in the efficient utilization of the manpower available. The supervisor should schedule his workload in such a way that planned absences of key workers will not unduly interrupt the daily routine. When scheduling the workload, he should keep in mind the skill level required for the various tasks and assign individuals to jobs in such a way that the work may still progress if any worker is unexpectedly absent.

OPERATION WITH MINIMUM EXPENSE AND WASTE

The efficiency of any operation is directly related to the expense involved. The shop supervisor has responsibility for ordering and accounting for parts and materials. He must impress upon his men the need for being thrifty in the use of these materials. There are many ways to economize, and the supervisor and his senior petty officers should always be on the alert for opportunities to point out these ways to the less experienced individuals.

Methods of avoiding waste and unnecessary expense should be included in the shop training program.

PROVIDING FOR INTERRUPTION

During an average workday, occasions will arise when personnel have to leave their working spaces for one reason or another, thereby delaying the scheduled work. Some delays can be anticipated; some cannot. Among the delays that can be anticipated are training lectures, immunization schedules, flight schedules, rating examinations, meals, and watches and other military duties.

Before making personnel work assignments the supervisor should determine what delays can be anticipated. It may be possible to arrange assignments so that work interruption is held to a minimum. When estimating the completion time of an aircraft maintenance task, the supervisor should allow for these predictable delays.

UNFORESEEN DIFFICULTIES

Some difficulties are impossible to predict. The weather, for instance, cannot be relied upon for full cooperation in the maintenance effort. The supervisor must have a flexible schedule planned to provide for such events if he expects to contribute maximum support to his unit. The flight schedule itself is seldom ever completed without a few changes. Usually these changes will involve a rearrangement of previously planned maintenance tasks. Again the supervisor must be as well prepared for such interruptions as possible and be able to reassign his men, if necessary, with the least amount of confusion and loss of time.

SHOP ORGANIZATION

A well-organized shop will provide a safe and comfortable working area, allow for maximum use of space available, and produce the most toward the maintenance effort.

SHOP LAYOUT

The average Chief or First Class Petty Officer may never have the opportunity of planning the layout of an Avionics shop in a new facility. In almost every case, the new supervisor will take charge of an already functioning division or, when his squadron or unit moves to a new base, he and his crew will usually be assigned to spaces already basically equipped. In either case, a reevaluation of the shop's layout is indicated. This reevaluation should include checking the most recent applicable allowance lists to see if the shop equipment allowances have been changed in any way. There is no use relocating equipment which involves rewiring work if improved replacement models are authorized and available.

A change in assigned aircraft model designation may call for a reevaluation of the shop layout.

When planning for new installations, the supervisor should utilize the Design Guide for Avionics Shop Power Distribution, NavWeps 01-1A-512.

The ideal setup contains enough space to have all the avionics shops in separate spaces in a centrally located area. Since this is not always possible, the supervisor must decide what shops are to be combined, if any, and in what areas of each space the appropriate equipment is to

771

be installed. This decision should be based on factors of safety, economy, functional compatibility, and convenience.

The shop layout plan should make provisions for an information or bulletin board upon which may be posted safety posters, maintenance posters, instructions and notices, plans-of-the-day, and such other information as is appropriate from time to time. The bulletin board should be located in a prominent place in the shop, preferably near the entrance where everyone asigned will have to pass at some time or another during the day. Material on the bulletin board should be changed frequently, expired notices promptly removed, the current plan-of-the-day posted early, and other posters and materials rotated periodically. If the same material is presented in the same format every day, it will not be long before the men begin to ignore the bulletin board and purposes for having it are defeated. New arrangements are noticed and interest is stimulated with variety.

BENCH ARRANGEMENT

Following the determination of what shops are to occupy what spaces or areas within a space comes the arrangement of furniture and equipment for the various shops.

The arrangement of the shop furnishings should be made on the basis of utility rather than appearance. Moving an item of equipment into an out-of-the-way corner may greatly improve the appearance of the shop but at the same time reduce the efficiency of personnel using the equipment and may possibly create a safety hazard. A good rule to follow is to locate equipment where it can be safely used by the greatest number of people with a minimum of effort in the least amount of time.

In view of the fact that standard avionics workbenches are normally used in shops where actual maintenance and testing of equipments are accomplished and that these benches usually become fixed in their position (due to test harness and cabling arrangements) there will be few benches or worktables to consider. Worktables or workbenches that are not permanently installed should be positioned with respect to fixed equipment so that they can be safely, quickly, and easily reached when work is being performed that requires their use. In an area where intricate maintenance functions are to be performed, such as disassembly and repair of miniature components, consideration should be given to special interference-free type lighting.

If a separate shop space is not provided for classified equipments, then placement of these equipments in a section of the shop where the physical arrangement provides limited or controlled access is desired.

SAFETY

Operational readiness of a maximum number of aircraft is necessary if naval aviation is to successfully perform its mission. Keeping its aircraft in top operating condition is the principal function of naval aviation maintenance personnel. It is essential that maintenance work be performed with a minimum of injury to personnel and damage to equipment and aircraft.

Aircraft maintenance is, to some extent, naturally hazardous due to the nature of the work, the equipment and tools involved, and the variety of materials required to perform many repairs and maintenance functions. Factors which can function to increase or decrease these hazards are (1) the experience levels and mental attitudes of assigned personnel, and (2) the quality of supervision of the maintenance tasks. Thorough indoctrination of all personnel is the most important single step in maintaining safe working conditions.

The concept of aircraft maintenance safety should extend beyond concern for injury to personnel and damage to equipment and aircraft. Safe work habits go hand-in-hand with flying safety. Tools left in aircraft, improper torquing of fasteners, and poor housekeeping around aircraft can cause conditions which may claim the lives of flying personnel as well as cause strike damage to aircraft. Safety on the ground is equally as important as safety in the air.

A recent type commander letter states in part, "While the increased complexity of our modern aircraft is a factor, it is noted that a large number of maintenance-error-caused accidents and incidents are due, not to complexity of equipment, but to lack of supervision and technical knowledge. Many mistakes are simple ones in routine maintenance."

Safety in aircraft maintenance depends largely upon the supervisory personnel. The standards of quality which they establish are directly reflected in the quality of the aircraft maintenance. The primary duty of the senior petty officers

is to supervise and instruct others rather than to become totally engrossed in actual production. Attempts to perform both functions invariably result in inadequate supervision and greater chance of error. Supervisors must exercise mature judgment when assigning personnel to maintenance jobs. Consideration must be given to each man's experience, training, and ability.

Sometimes overlooked in a maintenance program are the considerations generally grouped under the term "human factors." These factors are important in that they determine if an individual is ready and physically able to do work safely and with quality. Supervisory personnel should be constantly aware of conditions such as general health, physical and mental fatigue, unit and individual morale, training and experience levels of personnel, and other conditions which can contribute in varying degrees to unsafe work. Not only is it important that proper tools and protective clothing and equipment are available for use, but also the insistence by maintenance supervisors that they are used is of increasing importance with modern high performance aircraft. For example, maintenance personnel are sometimes negligent in the wearing of protective hearing devices in high noise areas.

There are several areas in which the shop supervisor can effectively work to minimize accidents incident to aircraft maintenance. Among these are continuing inspections of work areas, tools, and equipment; organization and administration of safety programs; correct interpretation of safety directives and precautions; and energetic and imaginative enforcement of them.

Technical knowledge also plays a large part in a good maintenance safety program. The complexity of our modern equipment demands the attention of well-informed and expert maintenance personnel; otherwise, our weapons system cannot be operated and maintained. Technical knowledge is a function of education and training which, incidentally, does not end with graduation from school. Graduation is only the beginning. Any technician worthy of his rating is continually training and learning through self-study and application, and through a personal desire for proficiency and self-betterment. But technical knowledge by itself is not sufficient unless it is coupled with an old-fashioned craftmanship that receives gratification and keen satisfaction in doing any job well. The man who wishes to contribute to safety and reliability improvement must know his job and must develop professional pride in the quality of his work.

It is a continuing duty of every person connected with aircraft maintenance to try to discover and eliminate unsafe work practices. Accidents which are caused by such practices may not take place until a much later date and their severity cannot be predicted. The consequences may range from simple material failure to a major accident resulting in serious injuries or fatalities.

ELIMINATION OF HAZARDS

Most accidents which occur in noncombat operations can be prevented if the full cooperation of personnel is gained and vigilance is exercised to eliminate unsafe acts. The supervisor should diligently inspect work areas, tools, and equipment to detect potentially hazardous and unsafe conditions and take appropriate corrective action. Since maintenance personnel will be working in the shop, in the hangar, and on the line all of these areas should be included in the supervisor's inspection. He should check for explosion or inhalation hazards due to improper ventilation of working spaces, or careless handling of materials.

Spilled oil, grease, and chemicals should be wiped up promptly, and all rags used should be disposed of in covered metal containers.

Handtools should be in good shape, of the proper type, and used only for the purpose for which they were designed.

Fire hazards present another serious problem. "No Smoking" rules should be strictly enforced. Ground wires should be installed on every aircraft during maintenance to eliminate dangerous static electrical buildups.

GROUNDING

Grounding power tools and other equipment is a must and the supervisor is the man to see that this is done. It should not be necessary for a technician to be killed to once again emphasize the absolute necessity that portable power tools and other equipment be properly grounded. The importance of installing safety grounds to the cases of power tools or equipment must be stressed as a case of life or death-that is exactly what it is.

Another aspect of this problem, which deserves attention in a poor safety ground or one that is wired incorrectly. This may be more dangerous than no ground at all. A poor ground is dangerous because it does not offer full protection, yet it lulls the user into a false sense of security. The incorrectly wired ground is a hazard because transposing one of the line wires and the safety ground makes the shell of the tool "hot" the instant the plug is connected. Thus the unwary user is trapped unless, by pure chance, the safety ground is connected to the grounded side of the line on a single-phase grounded system. In this case, the user again goes blithely along using the tool until he encounters a receptacle which has its wires transposed.

The need for a safety ground is not hard to realize when you know that a few years ago statistics showed that, over a given period, 50 percent of the deaths in the Navy due to electric shock were caused by 115-volt electric potentials.

The reason for this high percentage is as follows: When the current through the body nears 100 milliamperes, death is almost certain. The body resistance, assuming dry skin, varies from about 1,000 to 500,000 ohms. With a 115-volt potential, a body resistance as low as 1,150 ohms can produce the necessary 100 milliamperes. With perspiration or water on the victim's hands, the body's resistance can go as low as about 300 ohms, resulting in a current of 384 milliamperes, which is normally lethal.

Portable power tools afford you an excellent opportunity to become part of a circuit. For example, if the motor winding is shorted to the case, the case will be at the same potential as the power applied. Then the path of least resistance may be you.

These facts caused SecNav to formulate the policy of grounding any exposed, noncurrent-carrying parts of electrically operated equipment powered from supply circuits of more than 50 volts. Several safety measures have been adopted to implement this policy.

In an effort to make certain that a safety ground is used, a requirement has been established for a 3-wire, color-coded cord with a polarized plug having a ground pin.

Since the polarized plug can be connected only to a mating receptacle, the user has no choice but to use the safety ground. (Adapters to change three-prong plugs to two-prong plugs are sometimes furnished, but they should never be used with power tools.) Supervisors should insure that the ground pin is not removed from the polarized plug. The color coding has been standardized to conform with the National Electric Code. All new tools which are properly connected use a green wire as the safety ground. The wire is attached to the metal case of the tool at one end and to the grounding pin in the connector at the other end. It normally carries no current, being used only when the tool insulation fails to bypass the current around the user to ground. Black and white leads are used as the current-carrying conductors: the white lead is the power ground of a single-phase system, and the black lead is hot.

The three-pin plugs and their receptacles have been designed to minimize the possibility of incorrect wiring. Looking at the end of a plug, you will notice that the pins are constructed so that they can be put into the receptacle in only one position. The ground pin is the longest and therefore will mate first and break last, insuring that the safety ground is connected at all times when power is applied to the circuit. In addition, the plugs are usually color coded. The three-prong plugs ordered under FSN N5935-280-2380 (Connector Plug, Electrical) have color-coded screws: The terminal screw on the safety ground prong is painted green; the neutral prong and screw are silver; and the terminal screw on the hot pin is brass. Thus, there should be no confusion when installing this type of plug.

One fact must be kept in mind when installing safety ground hardware. Although all portable power tools need this feature, some items of sensitive test equipment should not have their cases grounded. Grounding the case of some VTVM's, for instance, creates a possible ground loop which will support spurious signals, thereby hindering measurement accuracy.

If a cable requires replacing, be certain to replace it with the proper color-coded cord; and make sure that the green conductor is connected to the shell of the equipment. If the shell consists of more than one piece, make sure that all pieces are connected. Clean off any paint, and scrape the metal beneath it to make a clear, clean surface at the point of connection.

When it is necessary to use an extension cord, use only the type that has a grounded

plug attached to one end and a grounded receptacle (suitable for connecting to the grounded tool plug) on the other.

If the tool or equipment is adequately grounded through a supporting bracket or bulkhead fastener, you need not use the ground cable. For your own protection, however, you should check the resistance to ground with a low-reading ohmmeter to be certain that the grounding is adequate (less than 0.1 ohm is acceptable). If the resistance indicates greater than 0.1 ohm, use either a separate ground strap or a three-wire cord; and check the ground connection to be certain of a good contact.

When installing a new cord or checking the tool for safety, examine the cord connections carefully. The cable wires should terminate in a standard crimped or solder type lug or connector; or, if stranded wire is used without a lug, the ends should be solder dipped. Form the wire into a loop (in the direction of the screw rotation) around the connecting screw; and make absolutely certain that no loose, fine strands of the flexible wire cord protrude to cause an accidental contact with the shell of the tool, receptacle, or plug.

High Voltage

All radars employ voltages which are dangerous and may be fatal if contacted. Practical safety precautions have been incorporated into every radar system; however, when the most basic rules of safety are ignored, the built-in protection becomes useless.

The following rules are basic and should be followed at all times by all personnel when working with or near high voltage circuits:

1. CONSIDER THE RESULT OF EACH ACT—There is absolutely no reason for individual to take chances that will endanger his life or the lives of others.
2. KEEP AWAY FROM LIVE CIRCUITS—Do not change tubes or make adjustments inside the equipment with high voltages on.
3. DO NOT SERVICE ALONE—Always service equipment in the presence of another person capable of rendering assistance or first aid in an emergency.
4. DO NOT TAMPER WITH INTERLOCKS—Do not depend on interlocks for protection; always shut down equipment. Never remove, short-circuit, or tamper with interlocks except to repair the switch.
5. DO NOT GROUND YOURSELF—Make sure you are not grounded when adjusting equipment or using measuring equipment. Use only one hand when servicing live equipment.
6. Do not energize equipment if there is any evidence of water leakage; repair the leak and wipe up the water before energizing.

These rules, teamed with the idea that "voltage is not a respecter of persons" and that personal caution is your greatest safeguard, may prevent serious injury or even death.

ORGANIZATION AND ADMINISTRATION OF SAFETY PROGRAMS

In accordance with the Navy policy of conserving manpower and material, all naval activities are required to conduct effective and continuous accident prevention programs. The organization and the administration of a safety program are part of the requirements of the supervisor. The safety program must be in accordance with local instructions and based on information contained in the Navy safety precautions manuals which are presently undergoing a revision. Work methods must be adopted which do not expose personnel unnecessarily to injury or occupational health hazards. Instructions in appropriate safety precautions are required to be given and disciplinary action taken in case of willful violations.

The shop safety program will generally involve three areas of attention—the posting of the most important safety precautions in appropriate places, the incoporation of safety lessons in the formal training program, and frequent checks for understanding during the day-to-day supervision of work.

Posted safety precautions are more effective if they may be easily complied with; for example, a sign on the electronic test bench reads "ground high voltage of terminal before working on or near video indicator." Thus, a high voltage grounding probe should be installed in a convenient location.

Fixed posters and signs should be renewed frequently and not allowed to become rusty, faded, or covered with dust and dirt. General safety posters on bulletin boards and other places should be rotated often to stimulate interest. Appropriate safety posters may be obtained from the squadron or unit safety officer.

The formal safety training sessions should utilize films, books, visual aids, or any other

775

suitable technical material. The men should be told more than just what or what not to do. Each safety subject should be explained in detail. The results of unsafe acts are usually the most dramatic and easiest remembered. Causes of accidents and contributing factors should be reviewed and analyzed. Many good ideas for accident prevention have been developed in training sessions.

An extensive series of lessons may be developed over a period of time as latent hazards are recognized, and this will aid in keeping the sessions interesting while avoiding too frequent repetition.

It may be well to mention the new man in the shop at this point. A separate safety indoctrination lesson which covers all the major hazards of the shop should be given the new man as soon as he reports for work. The supervisor with an effective safety program and an excellent shop safety record will take steps necessary to make sure that the new man is properly instructed, so as to prevent his being hurt.

In the third area of safety program administration—followup, the supervisor will do well to delegate authority to his subordinate petty officers to assist him in monitoring the program. Also included in the followup area is a responsibility of the shop supervisor to inquire as quickly and thoroughly as possible into the circumstances of accidents and reports of unsafe practices and take action or make recommendations.

Safety precautions are designed to cover usual conditions in naval activities. Commanding officers and others in authority are authorized to issue special precautions to their commands to cover local conditions and unusual circumstances. The shop supervisor will have to apply both sets of rules in the administration of his shop safety program.

Safety directives and precautions should be followed to the letter in their specific application. Should any occasion arise in which any doubt exists as to the application of a particular directive or precaution, the measures to be taken are those which will achieve maximum safety.

When new safety posters or precautions are posted, it is the responsibility of the shop supervisor to correctly interpret their application to his men. In this way he will be able to achieve a unity of thought and action in the observance of the required safety rule.

The organization's safety officer is available to assit in interpreting and suggesting ways of implementing various safety directives and precautions. Current directives require that a safety officer or safety engineer be assigned as head of the safety department, division, branch, or section, whichever is applicable, at all shore stations.

In most instances the hazards involved and the applicable precautions for a given type of work are the same whether the work is done afloat or ashore.

RADIOACTIVE TUBES

Radioactive material is used in quite a number of spark gap, TR, glow lamp, and cold cathode tubes.

In many cases the personnel charged with maintenance of equipment that contains radioactive material are not aware that they are handling radioactive matter. Even if they do know, they are quite likely to take the matter too lightly.

Radioactive materials are intentionally added to the tubes to produce a continuous supply of ionized particles in the tubes. This assures that the tubes will always operate at the same voltage.

The radioactive material causes the tube to produce a continuous supply of ionized particles whether the tube is in storage, in transit, in the equipment, or in disposal containers. The general concept is that ionization occurs only when the keep-alive voltage is applied to the tube. This is fallacious, since the voltage only increases the rate of ionization; it does not affect the rate of decay of the radioactive material.

Radiological Hazards

Radioactive tubes, as normally used and stored aboard stations and ships, do not subject personnel to a dangerous amount of external radiation. As long as the radioactive tubes are not broken, the hazard is slight; but as soon as the tubes are broken, the hazard is increased because internal radiation is then possible by inhalation of radioactive materials. However, they should be handled very carefully to prevent breakage; also, it is recommended that technicians do not remove radioactive tubes from cartons until they are ready to be used. This will preclude the possibility

of the accumulation of unpacked tubes and help prevent accidental breakage.

Handling Broken Tubes

When a radioactive tube has been broken, it is advisable to observe the following rules, which apply when any material is contaminated by radioactivity:

1. Contact a medical officer.
2. Never permit any material contaminated by radioactivity to come in contact with any part of the body at any time. Wear rubber or plastic gloves at all times when it is necessary to handle radioactive wastes or broken radioactive parts.
3. Do not bring food or drink into the contaminated area or near any material that is radioactive.
4. Immediately after leaving the contaminated area, if you have handled radioactive material in any way, remove any clothing which might have become contaminated, and wash your hands and arms thoroughly with soap and water, especially before eating, drinking, or smoking.

Disposal

In order that the Atomic Energy Commission (AEC) shall have cognizance of all disposal areas, amounts deposited in each area, and disposal procedures, SecNav Instruction 4555.1 directs that all naval activities shall dispose of radioactive waste by transferring them to an activity licensed by the AEC or to an AEC land disposal site, except in certain cases which are described in the instruction.

In general, radioactive electron tubes should not be disposed of individually, but should be collected in a designated container with a tight-fitting lid and suitable markings until a reasonable quantity for disposal has been gathered.

Tube and Container Markings

There are two types of marking or labeling of commodities and their containers, based on the level of activity of the radioisotope contained. Detailed information concerning the requirements of these markings and a list of the radioactive isotopes can be found in MIL-M-1959OC.

Type I or type II markings must be placed on the radioactive source enclosure and on each surrounding container so that the presence of the radioactive material can be readily recognized and its location determined.

The color of both type I and type II symbols and the words "DANGER" and "CAUTION" will be magenta (purplish red) on a yellow background. Type I marking is as shown in figure 5-1. The words "controlled disposal required" mean that, as directed by SecNav Instruction 4555.1, naval activities must dispose of radioactive wastes through organizations licensed by AEC or through AEC land disposal sites whenever practicable. AEC controls the disposal locations and the amount of radioactive material deposited at each location in order to reduce potential hazards to the public.

Type II marking is shown in figure 5-2. The words "accountability required" means that each organization that uses and/or stocks radioactive tubes must keep records showing the receipt, transfer, export, and disposal of such items in accordance with existing instructions. For special instructions concerning type II markings, refer to MIL-M-1959OC.

Figure 5-1.—Type I marking.

Figure 5-2. —Type II marking.

CARE OF TOOLS AND TEST EQUIPMENT

One of the problems of the supervisor will be the care and proper use of tools and test equipment. It is sometimes difficult for some men to realize the need of a special effort in the care of the tools and other equipment necessary in the performance of their work. There are two main reasons for taking special care of these items: First, maintenance would be impossible without them; and second, they are costly and therefore are sometimes in limited supply.

The care of these items includes using them only for the purpose for which they were designed. A case in point is the use of the "Phillips" and "Reed and Prince" screwdrivers interchangeably. Most technicians have seen the tool and equipment damage caused by this malpractice. Other items such as soldering irons and guns, files, test leads, and small meters are among those which receive the most abuse.

Test equipment is expensive and delicate; therefore, the care and proper use of this equipment will be of great concern to the supervisor. If the care of such equipment is not emphasized, it will soon deteriorate to a point where it is useless and, in fact, may even become dangerous. Meter leads must be properly stowed to prevent loss or damage; and if a cover is provided, it should be installed when the meter is not in use.

A system of stowing tools and other equipment must also be devised. The place for all tools should be marked, and everything not being used should be returned to its proper place. Toolboxes issued to shop personnel should contain a duplicate inventory list of tools issued with the box. The original should be kept in the shop files. Periodic inventory of these toolboxes is necessary since it is impossible to operate without an occasional loss or damage of tools.

TRAINING OF PERSONNEL

Training of personnel is a necessary function and one of the most important responsibilities of the supervisor. Even if a supervisor is fortunate enough to have a group of men who are highly skilled and well trained, he will find that training is still necessary. For example, the training of strikers and lower rated men for advancement in rating examinations is a continuing, never-ending process. The Navy rotation policy being what it is, all men will eventually be transferred and replacements will be received aboard. The replacements will, in most instances, require training before they can be relied on to take their places as effective members of the shop organization. These and similar problems require the supervisor to be well versed in the several aspects of training—able to set up as well as conduct an effective training program for assigned personnel.

ORGANIZING A TRAINING PROGRAM

Organizing a shop training program involves such considerations as determining objectives of the training program, selecting and qualifying instructors, making arrangements for classroom space, phasing the training program with the scheduled workload, procuring training aids, and determining teaching methods for each lesson or lesson series.

778 ٢٢٢

The subject matter areas to be included in the shop training program are (1) material relating to maintenance of aircraft supported, (2) general material required by the men for advancement in rating examinations, and (3) material relating to safety. In most cases lessons will fall under more than one of the subject areas.

Once it has been determined what publications will adequately cover the subject areas, the material must be divided into lessons, and lesson guides prepared. It will be very helpful to assign numbers to the lessons and provide a personnel training progress record for each individual. These will provide a handy index to the state of training of the shop personnel as a whole.

Whether the shop supervisor teaches the lessons himself or assigns other petty officers to conduct them depends on the state of training of his first and second class petty officers. A requirement for advancement for third class petty officers and nonrated personnel is satisfactory completion of the correspondence course based on Military Requirements for Petty Officer 3 & 2, NavPers 10056-B. Chapter 9 in that text book sets forth some of the basic principles of training in general and teaching in particular.

An advancement requirement for second and first class petty officers is satisfactory completion of the correspondence course based on Military Requirements for Petty Officer 1 & C, NavPers 10057-B. The latter test expands and amplifies training theory and introduces job analysis, training aids, and testing. For the first time in his career the prospective First Class Petty Officer is required to demonstrate his ability to formally teach, use various training aids, and prepare and administer written tests. In order to demonstrate correct instructional techniques the shop supervisor may elect to teach certain lessons himself or assign them to a competent instructor for the same purpose. Later he may assign less proficient petty officers as instructors so that they may acquire the experience necessary for completing their practical factors for advancement.

If at all possible, training sessions should be conducted at the same time of day and on a regular schedule. Factors to consider when scheduling lessons are usual flight schedules, meal hours, watches, availability of classrooms, and aircraft inspection schedules.

Some lessons are better suited for one type of instructional technique than others. The type of presentation for each lesson should be planned in advance. This will also facilitate the rotation of the lessons among the petty officers who require experience in teaching.

The effectiveness of aviation technical training is greatly enhanced by the use of training aids. The shop supervisors should always be on the alert for material that can be utilized as training aids. He must be aware of the existence of applicable training films and, if they are available, schedule them for showing in conjunction with specific lessons. The squadron or unit training officer may usually be depended on to supply training aids in support of shop safety presentations.

When planning a training program, the supervisor should decide where the classroom sessions should be conducted. The space selected should preferably be in a quiet area or at least one with a minimum of noisy distractions. The area should be large enough to accommodate the expected student load and be well lighted. Adequate ventilation will help keep the men awake and interested in the presentation. Convenience is another factor in the selection of classroom space. Some of the desirable space characteristics may, on occasion, have to be sacrificed in order to find a classroom nearer to the working area.

Training procedures are of two general types—formal training which can be scheduled, and informal training which cannot be scheduled.

Formal Training

Formal training is normally conducted in the classroom through lectures, supplemented by required reading and implemented by the use of all available visual aids. The schedule is prepared and published periodically by the maintenance officer. It lists the time of the training, the location of the classroom, names of the men who are to attend, subject of the lesson, and the name of the instructor.

Lesson guides are prepared by the division officer and chief or first class petty officers who are qualified to do so. The lesson guides should contain the title, objective(s), time to be consumed in presenting the lesson, list of instructional aids, list of references, outline for presentation, and a summary of the lesson.

When a petty officer has been assigned to instruct a given lesson, it is his responsibility

779

to procure a copy of the lesson guide and from it prepare his lesson plan. Lesson plans are prepared by each individual instructor, based on the lesson guide; and though they may differ from instructor to instructor, they must adequately cover the subject.

SPECIALIZED TRAINING.—At most major naval air stations there will be a Naval Air Maintenance Training Group which offers courses of varying lengths on specific aircraft and systems. These courses are normally made available through the replacement air wing training division.

Some Naval Air Rework Facilities offer special courses on repair of certain electronic equipments. These, as well as other C-type courses, provide the supervisor with a source of specialized formal training that the man may attend on a returnable basis.

In addition to the courses mentioned previously, engineers of the Naval Aviation Engineering Service Unit are ready, willing, and able to assist in training of maintenance personnel. These people usually have the latest "Hot Dope" and should be consulted at frequent intervals.

Informal Training

Informal training is the practical instruction of men in the performance of maintenance tasks by means of demonstration and imitation under personal supervision in the shop or on the operating line. Nearly every maintenance task that is undertaken presents an opportunity for on-the-job training. The experienced men of the division are utilized as fully as possible in demonstrating and imparting their skills to the less experienced.

Under this system, the trainee has the opportunity to actually do the job under the supervision of an experienced petty officer. The only equipment necessary is the job itself. It is necessary, of course, that the instructor have an interest in the job and the skill to do it well. The striker or trainee will learn by seeing the job performed, and he will gain experience by having a chance to participate in the accomplishment of the job.

The nature of informal training makes regular scheduling impracticable. Actually, it is done at every opportunity. A training syllabus is prepared under the guidance of the maintenance officer, with content and scope corresponding with practical factor requirements of the personnel. On-the-job training is reported by the leading petty officer instructors and shop supervisors to the division officers on the training syllabus at regular intervals so that a close watch may be made on individual progress. The records are for review by higher authority and will point out the need for training in special areas as well as certain practical factors. The degree of success in on-the-job training depends on the degree of recognition by each individual of his responsibility to his outfit to impart his skill and knowledge to the man who is trying to learn.

TRAINING RECORDS

Since all men are not present at each unscheduled training period nor do they attend the same scheduled classes, it is apparent that they will become trained to different levels on different equipment. Obviously the supervisor must see that a record is carefully kept on each man, with an entry made each time he undergoes instruction.

Methods of recordkeeping are many and varied, but it is best to keep them in the most simple and easy-to-read form. The more elaborate the system, the more difficult it is to maintain. There are standard forms available which can be used for planning as well as for record purposes. These forms are designed to reduce recordkeeping to a minimum. Detailed information concerning recordkeeping methods can be found in Military Requirements for Petty Officer 1 & C, NavPers 10057-B.

JOB PRIORITY

Determining which jobs are to be performed first is one of the major responsibilities of the supervisor. This is an important phase of the maintenance operation because it will determine the use of facilities, men, material, and other equipment. The two major factors to consider when determining which job should come first are time and personnel required to complete the job.

Probably the most important single aid in estimating time and personnel requirements for aircraft maintenance tasks is the Periodic Maintenance Requirements Manual with its related cards, charts, and forms. Extensive time and motion studies of the various inspection requirements have been made and completion times are furnished in man-hours or man-minutes. These times also reflect routine

maintenance, adjustment, and replacement if required in connection with the aircraft inspection. They are calculated on the basis that the most efficient number of men are continuously employed and that all necessary equipment, tools, and parts are immediately available. The supervisor must consider all these factors from the knowledge of his individual personnel, supply, and equipment situation, together with an accurate determination of the extent to which the maintenance task at hand exceeds the inspection requirements if he is to reliably predict the completion time. While this procedure may seem rather involved at first, the new supervisor will find that it is based on sound management principles and that, with experience, his ability to accurately predict time and personnel requirements will speedily improve.

SCHEDULING

If possible, the supervisor should avoid scheduling several jobs that may require identical tools and equipments to be performed at the same time. This often results in confusion and loss of time.

It is also important to schedule activities so that work is accomplished in the proper sequence. This is especially important if men are working on several different phases of the same job.

Time must be allowed in the schedule for assignment of future routine work. This may make it necessary to rearrange the present schedule to insure that special jobs will not interfere with the accomplishment of this work.

ASSIGNMENT OF PERSONNEL

Work assignments should be rotated so that each man will have an opportunity to develop his skills in all phases of the work. When assignments are rotated, the work becomes more interesting for the men. Another good reason for rotating work assignments is that if one highly skilled man performs all the work of a certain type, the supervisor and the shop would be at a great disadvantage in the event the man is transferred from the shop. Less experienced personnel should be assigned to work with him in order to become proficient in his particular skill. Also, in order to broaden his knowledge of his rate, the expert on one job should be rotated to other tasks when there is no immediate need for his particular skill.

Strikers should be assigned to various tasks so that they will acquire experience on all kinds of jobs. A special consideration for the assignment of strikers to jobs is that they should be assigned progressively to jobs of ascending levels of difficulty. A striker may be a useful assistant on a complicated job, but he may not understand what he is doing unless he has worked his way up from basic tasks.

CHECKING PROGRESS AND EVALUATING PROCEDURES

The assignment of work is only the beginning of job processing. The man in charge must know his men and have a fairly good idea of each man's skills and abilities. He must also be aware of each man's knowledge regarding the operation of equipment and the accomplishment of repair work.

The best way in which the supervisor can obtain this knowledge is to make frequent inspections and check the progress of work being performed. In that way he will have a good idea as to which jobs, or which men, will require the most supervision.

When checking the progress of work, the supervisor should make sure that the men are observing proper safety precautions in regard to themselves and the equipment they are operating. In addition, he should see that each man is using the proper tools, and note the quality of the work being performed.

In case of any doubt, he should check to see that his instructions are understood and that the work is being performed correctly. If necessary, he should provide additional instructions to give a better understanding of the job or to improve workmanship. By frequently talking to the men and answering their questions, the supervisor can prevent time and material waste, as could be the case if he were not available to give the correct details.

Complications may develop on some repairs which may require additional planning and revised repair procedures. By observing the progress of various jobs, and whether they are ahead or behind the planned schedule, the supervisor will be able to change the schedule in order to prevent any major work stoppage.

INSPECTING COMPLETED WORK

When a job has been completed, the man in charge is responsible for inspecting and approving the work. Inspection is necessary to

insure that the repair job or the replacement parts will be satisfactory. A thorough inspection normally requires that it be accomplished both visually and by means of measuring instruments. In addition, specific operational tests are performed to check the condition of repaired equipment.

The supervisor is responsible for determining whether the repair job, including replacement parts, meets the following standards:

1. Have the repair parts been correctly installed in accordance with instructions?
2. Is the repaired item or replacement part free from defects in material and workmanship?
3. Have all parts or accessories to the repaired equipment been replaced or reinstalled correctly?
4. Has the proper replacement part been used in making repairs?
5. Has the part or item been properly checked and certified ready for service?

The existence of a properly functioning quality control division in no way decreases the responsibility of the shop supervisor for the quality of work accomplished. Since the work was performed by shop personnel under the direct supervision of the senior man, the quality of the work is fundamentally a shop responsibility.

CHANGES AND BULLETINS

Changes and bulletins are eventually issued to the shop responsible for the subject equipment in the form of maintenance instructions. These instructions prepared by the division officer with the aid of the division or shop supervisor, are an interpretation of the directive. It then becomes the responsibility of the supervisor to instruct and supervise the installation, marking, and recording.

ACQUIRING AND INSTALLING CHANGE KITS

Change kits are not normally ordered directly by the shop concerned. When a directive is received requiring a change kit, maintenance control or designated personnel of the maintenance division, with the assistance of the shop supervisor, if requested, will order the kit.

Installation of change kits is governed by the directive concerning the change or bulletin. Some must be installed immediately in the event safety is involved. Others have specified time periods allowed as determined from the directive. In any case they should be installed as soon as practicable so as to take advantage of the new configuration. The supervisor must insure that workmanship is of the highest caliber that accepted electrical and electronic installation practices are adhered to, and that detailed instructions, when included, are followed precisely.

MARKING EQUIPMENT AND RECORDING

Change kits are normally ordered and issued against an aircraft bureau number. This means that marking the equipment and keeping complete and up-to-date records is necessary to prevent confusion and loss of time. If correct marking and recording of equipment changes are not kept current, it could affect aircraft availability and scheduling.

Information concerning the type and manner of marking equipments in which a change has been installed is described under the directive heading "identification." In some cases the directive refers to Electronic Material Bulletin 1-54 as the source of information for identification markings. In all cases marking must be accomplished at the time the change has been installed.

If a change is made to plug-in assemblies or subassemblies which are interchangeable between equipments, the identification marking must be applied to the chassis of these assemblies or subassemblies. In addition, this identification marking is also to be placed on the front panel of the equipment.

No markings are to be applied to dust covers, cases, mounting bases, etc., unless a change is made to these specific items. A material marking kit for use by maintenance activities may be obtained through normal supply channels, although most change kits include the necessary equipment for marking.

After the change has been correctly installed and the equipment properly marked, records must be made to reflect the change. Recording is accomplished by the use of history cards, file copies of maintenance instructions (SAMI, CAMI, etc.), and aircraft logbooks.

If the equipment has a history card, this card should be kept current. History cards can be used as a quick reference to equipment configuration; however, if history cards are not required and not used, the file copy of the maintenance instruction will serve the same

782 185

purpose. When directives require a logbook entry, these entries are recorded by the persons in maintenance control assigned this responsibility.

The main thing for the supervisor to keep in mind is that a record of these changes must be kept, for without them there will be nothing but confusion.

CHAPTER 6

MAINTENANCE PROCEDURES AND SPECIAL PROBLEMS

The term "testing," as used in this chapter is considered to consist of measurements, tests, and checks. When these measurements, tests, and checks are applied to electronic equipments (or systems), they may provide information which establishes an acceptable condition, or they may provide information of undesirable conditions which exist in these equipments.

In the former instance, the testing (and inspection) proves that the equipments are operating within tolerances, and results in establishing a form of maintenance which is preventive in nature. In the latter instance, the testing (and inspection) exposes conditions which are undesirable, and which must be corrected if the equipments are to perform as designed. The result of this testing establishes another form of maintenance which is corrective in nature.

By applying both preventive and corrective maintenance, electronic equipments are kept in continuous service at optimum or peak performances that are reasonably close to the standards set by the manufacturing specifications.

Senior technicians should study and constantly refer to the available maintenance publications covering the equipments used by their activity. They should stand ready to answer questions about equipments, and to outline the various steps necessary to correct possible troubles.

MAINTENANCE PROCEDURES

Performance testing data, along with other maintenance information, is covered in the Service Instruction Manual for each particular equipment. This information has been written to enable the technician to make an intelligent evaluation of the operating capabilities of that equipment; at the same time the data serve as a gage for the measurement of equipment efficiency. The standards are designed to insure that equipments operate at maximum efficiency at all times, and to reveal any change from this optimum performance, thus indicating the need for corrective measures.

The information presented in these manuals gives the technician a step by step performance check with all the test connections and test equipment clearly indicated for each step. Performance testing is discussed to show the relationship between that type of testing and preventive maintenance, as a means of emphasizing the final results may indicate the need for corrective maintenance. Both preventive maintenance and corrective maintenance are discussed in the following paragraphs. Troubleshooting—considered as the principal form of corrective maintenance—is analyzed in detail.

PREVENTIVE MAINTENANCE

The best maintenance work is preventive in nature, potential failures being detected and corrected before they have a chance to develop. Preventive maintenance is defined as those measures taken periodically, or when needed, to achieve maximum efficiency in performance, to insure continuity of service, and to lengthen the useful life of the equipment or system. This form of maintenance consists principally of cleaning, lubrication, and periodic inspections aimed at discovering conditions which, if not corrected, may lead to malfunctions requiring major repair.

Performance Testing

A performance test is an operational check of equipment in which the performance specifications set by the manufacturer are carefully observed. It should be a part of an overall program of inspections and tests in which accumulative data on each equipment is systematically compiled.

Inspections fall into two main categories. First, there is the regular visual inspection of

the mechanical aspects of the equipments. This is conducted for the purpose of finding dirt, corrosion, loose connections, mechanical defects, and other sources of trouble. Second, there are functional inspections that are accomplished through periodic tests and through less frequent bench tests. To realize the most effective results from the regular functional inspections, a careful record of the performance data on each equipment must be kept.

The value of performance data records is demonstrated in a number of ways. Comparison of data taken on a particular equipment at different times reveals any slow, progressive drifts that may be too small to show up significantly in any one test. While the week to week changes may be slight, they should be followed carefully so that necessary replacements or repairs may be made before the margin of performance limits is reached. Any marked variations should be regarded as abnormal, and should be investigated immediately.

Another advantage in keeping systematic records of performance and servicing data is that maintenance personnel develop a more rapid familiarization with the equipment involved. The accumulated experience contained in the records furnishes a guide to swift and accurate troubleshooting.

Test Methods

The actual work of testing and servicing, as well as that of recording performance data, should be done systematically. While a logical sequence of steps is required, this does not imply the rigid necessity of making only a step by step progression. Working within the overall pattern of procedure, maintenance personnel should analyze the results obtained to eliminate unnecessary steps.

GENERAL RECEIVER TESTING. —Receivers are composed of a series of selective circuits, each stage of which is designed to refine and amplify the output of the preceding stage. The lowered efficiency of any one tube usually results in lowered overall efficiency of the receiver. The sensitivity of the receiver may also be decreased by the misalinement of the successive circuits, each of which may function in a suitable manner as a unit.

The function of a receiver is to receive (in a selective manner) a weak signal; therefore, an objective overall test on sensitivity is the most significant single check that can be made of the condition of a receiver.

Some receivers are provided with a built-in output meter, and others have an output meter equipped with a cord and plug to facilitate testing. The only other requirement for a sensitivity check is a suitable standard signal for the excitation of the receivers on the various bands. This signal may be provided by a calibrated signal generator with a dummy antenna coupled directly to the receiver input.

Any decrease in sensitivity should be corrected as soon as possible by following the appropriate remedial procedures. When using this method, use a megger before starting the tests to check for proper operation of both the radiating and the receiving antennas.

In addition to periodic checks on sensitivity, routine physical inspections must be made of the receiver and accessory units. Lubrication and cleaning schedules recommended by the manufacturer should be followed. Tubes should be tested sparingly, because frequent insertion and removal weakens socket contacts and causes noisy (or intermittent) operation.

Electron tube life extends to several thousand hours. Therefore, in equipment which is continuously operated and on which periodic sensitivity tests (or operation records) are made, tubes should be checked only when poor performance indicates such a need. When tubes are replaced in RF circuits, the circuit should be checked and, if necessary, realined to achieve normal sensitivity. Before new tubes are used, it is a good practice to check them on a tube tester of the transconductance type.

GENERAL TRANSMITTER TESTING. — In some transmitters, tube currents are automatically measured by self-contained instruments. If these readings are periodically recorded, the cumulative record bears the same relationship to the transmitter as a sensitivity check does to the receiver. When the emission of a large tube falls to 80 percent of normal rating, it should be replaced.

Ventilation and dust conditions present a greater problem in transmitters than they do in receivers, principally because there is more heat to be dissipiated. Because dust forms a film which absorbs moisture, the insulation resistance is lowered to a point at which flashover (arcing) can occur. Therefore, cleaning periods must be initiated and regularly followed. These periods will vary for different locations.

Insulators must be wiped, corroded metal parts cleaned, and arc-overs repaired. It is

possible to detect poor contacts by inspecting for evidences of local overheating (or arcing). Such contacts must be thoroughly cleaned and tightened. Likewise, it is important that the antenna connections be regularly inspected and cleaned.

CORRECTIVE MAINTENANCE

Corrective maintenance consists of the location and correction of troubles whenever an equipment or system fails to function properly. Location of the trouble includes the activities of evaluating reported discrepancies and troubleshooting.

The trouble may be corrected by mechanical or electrical adjustments, or it may be necessary to replace one or more parts.

Evualuation of Reported Discrepancies

When a discrepancy is turned in either by crew debriefing or on a "gripe sheet," the first thing to determine is whether the system or equipment is actually faulty. A mistake which is often made is removing the equipment from the aircraft before checking it.

The supervisor should have a prescribed procedure for technicians to follow in checking a discrepancy on equipment installed in an aircraft. Some suggested procedures that will aid in evaluating discrepancies are as follows:

1. Visual inspection. A visual inspection of the equipment in the aircraft may disclose frayed or broken wiring, loose connections (electrical and mechanical), or open circuit protectors, which could cause the malfunction.
2. Operational check. An operational check of the system can aid in analyzing the discrepancies and pinpointing the trouble to a particular unit. In some cases, it may disclose improper operating procedures—especially with newer type equipment or new personnel.
3. Performance checks. The use of portable test equipment, built-in meters, and special test equipment installed in some types of aircraft, will aid in making a performance test of the system in the aircraft. Performance testing, mentioned in the first part of this chapter, should be of great help in localizing the discrepancy to a particular unit which can be removed from the aircraft for repair, or in some cases, repaired in the aircraft.
4. Quality control inspections. Highly qualified senior technicians should be provided to conduct thorough inspections on all equipments prior to their installation in the aircraft. This quality control inspection should be a combination of the visual inspection, operational check, and performance check. This inspection will ascertain that each equipment is in proper operating order and completely mission ready.

Troubleshooting

Corrective maintenance is, for the most part, concerned with troubleshooting, which can be further divided into two phases. The first phase is system troubleshooting. It is based on the starting procedure, and is designed to isolate the malfunction to the unit in which the trouble exists.

The second phase is unit troubleshooting, and is designed to locate the trouble in the unit in which it occurs. In rare cases it is possible to determine which unit is at fault without following the system troubleshooting method to isolate the unit. However, most of the time it is impossible to determine which unit is at fault until the system method has been employed in whole or in part.

TROUBLE ISOLATION. —When abnormal operation has been traced to a particular stage or to a functionally related group of stages, its cause must be further isolated and identified as due to a particular faulty component or group of components. To do this it may be necessary to disassemble the equipment, either in whole or in part. After disassembly, the trouble may be immediately apparent through a mere visual inspection, whereupon the trouble should be corrected by repair or replacement.

If the trouble is not immediately apparent, a more detailed procedure should be followed to isolate and repair or replace the actual circuit component responsible for the failure. This procedure consists of tube checks, voltage and resistance checks, waveform analysis, and finally, repair or replacement of the defective component.

Supervisory personnel should insure that detailed trouble isolation procedures are in accordance with the applicable current Service Instruction Manual for the equipment being repaired.

TUBE TESTING. —Electron tube failures are responsible for a large percentage of troubles that occur in equipment or systems. However, if a particular system uses a great number of tubes, it is obviously impractical, and not good policy, for a technician to attempt to locate faults by general tube checking. Only when

the fault has been traced to a particular stage should any tubes be tested, and then only those associated with the improperly functioning circuits.

When replacing a tube in a circuit, the technician should note and record the positions of the equipment controls before changing the setting of any of them. If adjusting the controls with the new tube in place does not correct the abnormal condition, the controls should be returned to their original positions. Unless a reliable tube tester shows the original tube to be defective, the old tube should be returned to the original circuit.

After placing a new tube in a circuit, the technician must decide whether or not to discard the old tube. Certain types of tubes are capable of performing over a wide range of frequencies and driving voltages, so that their poor performance in one circuit does not necessarily preclude their use in another, less demanding circuit.

If a bin of used tubes is kept, each tube should be carefully labeled with a tag showing what circuit the tube was removed from, thus avoiding attempted reuse of the tube in the same type circuit. The tag should also indicate the operating conditions under which the tube "failed."

CAUTION: Steps should be taken to insure that no used tube is ever placed in a circuit whose failure would constitute a safety hazard or cause an aborted combat mission.

Any proposed procedure for reuse of old tubes should be submitted to the avionics officer for his review and approval.

In many high frequency equipments, the interelectrode capacitance of a tube is a significant portion of a tuned circuit; therefore, when tubes are changed, the tuning of the circuits may be upset. Thus, if too many tube substitutions are made, the unit may become misalined.

VOLTAGE MEASUREMENTS.—Since many troubles encountered in equipments and systems either result from abnormal voltages or produce abnormal voltages, voltage measurements are considered an indispensable aid in locating troubles. Testing techniques that utilize voltage measurements also have the advantage that circuit operation is not interrupted. Point to point voltage measurement charts which contain the normal operating voltages encountered in the various stages of the equipment are available to the technician. These voltages are usually measured between the indicated points and ground unless otherwise stated.

When making voltage measurements, it is good practice to set the voltmeter on the highest range initially so that any excessive voltage in a circuit will not damage the meter. To obtain increased accuracy, the voltmeter may then be set to the designated range for the proper comparison with the representative value given in the voltage charts.

If the internal resistance of the voltmeter and multiplier is approximately comparable in value to the resistance of the circuit under test, it will indicate a considerably lower voltage than the actual voltage present when the meter is removed from the circuit. The sensitivity (in ohms per volt) of the voltmeter used to prepare the voltage chart is always given on the charts. Therefore, if a meter of a similar sensitivity is available it should be used so that the effects of loading will not have to be considered.

When checking voltages, it is important to remember that a voltage reading can be obtained across a resistance, even if the resistance is open. The resistance of the meter and the multipliers forms a circuit resistance when the meter prods are placed across the open resistance. Thus the voltage across the component may appear to be normal when the meter is connected, and abnormal when it is disconnected. If the voltages appear normal on a faulty stage, the next step would be to perform a resistance check of that stage.

NOTE: Certain precautions are presented in Basic Electricity, NavPers 10086-A, as general safety measures pertinent to the measurement of voltages. Supervisors should ascertain that these precautions are adhered to by all personnel who are responsible for the maintenance of electronic equipment.

RESISTANCE MEASUREMENTS.—Defective components can usually be quickly located by measurement of the d-c resistance between various points in the circuit and a reference point or points (usually ground). This is true because a fault will generally produce a change in resistance values. Point to point resistance charts can be used advantageously at this time. The values given, unless otherwise stated, are measured between the indicated points and ground.

Before making resistance measurements, the technician must be sure that the power to the equipment under test has been turned off.

787

Since an ohmmeter is essentially a low range voltmeter and a battery, an ohmmeter connected to a circuit which already has voltages in it may be seriously damaged. The pointer may be deflected off scale, and the meter movement may be permanently damaged.

Filter capacitors must be discharged before making resistance measurements. This is extremely important when testing power supplies that are disconnected from their loads. If a capacitor discharges through the meter, the surge may burn out the meter movement. Furthermore, contact with a circuit containing a charged capacitor may endanger the life of the person making the test.

WAVEFORM COMPARISON. —The measurement and comparison of waveforms are considered to be very important parts of the circuit analysis used in troubleshooting. In some circuits (for example, pulse circuits) waveform analysis is indispensable. Waveforms may be observed at test points, shown in the waveform charts which are part of the maintenance literature for the equipment. It should be noted that the waveforms given in the instruction books are often idealized and do not show some of the details which are normally present when the actual waveform is displayed on an oscilloscope.

By comparing the observed waveform with the reference waveform, faults can be localized rapidly. A departure from the normal waveform indicates a fault that is located between the point where the waveform is last seen to be normal and the point where it is observed to be abnormal. (For example, if a waveform is observed to be normal at the grid circuit and abnormal at the plate circuit of the same stage, this indicates that the trouble lies in that stage or possible the input of the following stage.)

When waveforms associated with a multivibrator, a blocking oscillator, or a similar circuit are observed to be abnormal, replace the associated tube before making further tests. If the replacement tube does not provide the correct waveform, reinsert the original tube.

If there is no trouble present in an equipment or system, a waveform observed at a point in the equipment should closely resemble the reference waveform given for that test point. The reference waveforms supplied with maintenance literature are the criteria of proper equipment performance. However, test equipment characteristics or usage can cause distortion of the observed waveform, even though the equipment or system is operating normally. Several of the most common causes of these conditions are summarized as follows:

1. The leads of the test oscilloscope may not be placed in the same manner as those used in preparing the reference waveforms, or the lead lengths may differ considerably. This is particularly significant in the case of shielded test leads, where the capacitance per unit length is a factor.

2. A type of test oscilloscope having different values of input impedance, different sweep durations, or different frequency response may have been used.

3. The equipment operating (and servicing) controls may not have settings identical to those used when the reference waveforms were prepared. This condition is normally to be expected when servicing adjustments are made in terms of their effect on the shape and amplitude of an observed waveform.

4. The vertical or horizontal amplitudes of the reference and test patterns may not be proportional. This will produce apparent differences between the waveforms when actually there is no difference.

Whether or not a minor waveform discrepancy may be disregarded depends upon the type of circuit being traced. A minor discrepancy is not regarded as significant unless the nature of the discrepancy indicates faulty operation of the equipment. In general, time should not be wasted in searching for faults when relatively minor differences are detected between the reference waveforms and those obtained by test.

Modular Units

The demand for small, maintainable circuitry in military equipment has led to many different construction techniques. One of the most popular is modular construction. Since modular assemblies incorporate several subminiaturized features not found in conventional equipment, some specialized knowledge and tools are required for efficient repair and maintenance.

A few definitions are helpful in understanding the terms involved. A module is defined as "a unit or standard of measurement; a fixed dimension." A modular assembly has outline dimensions which are multiples of a module. An equipment which consists of replaceable assemblies (any type) is said to be of unitized construction. Modular construction, then, is a

type of unitized construction consisting predominantly of modular assemblies.

For example, think of a carton of cigarettes. If each pack were a modular assembly, the carton would represent an equipment of modular construction. Notice that the packs can be arranged differently without changing the outside dimensions of the carton. Although the cigarette packs are all the same size, the assemblies in many equipments are not.

The original concept of many modular assemblies was that they should not be maintained in the field. The intention was to replace the assembly and ship it back to some repair facility. As assemblies became more complex, the point was soon reached where the extensive supply system required for the replacement concept was too costly. Many equipments built during this initial stage were potted with some special ingredient to discourage maintenance personnel from tampering with the components contained within the black box.

When the Navy reassessed this concept, realizing that the Fleet must maintain every thing it could, most of the equipment manufacturers began to make components accessible. However, many technicians are still convinced that modular assemblies are impossible to repair. This conviction may stem from a lack of experience in working with the printed circuits and the other components in modular assemblies. While it is true that special tools and techniques are required, it is also true that satisfactory repairs can be made to any printed circuit by using just a little care and common sense. Actually, with a little experience, repairs can be made as easily as in conventional assemblies; sometimes more easily, because of improved accessibility.

Repair of Defective Components

One of the time-consuming elements of troubleshooting is the identification of specific components. In conventionally wired equipment, components are not always easy to locate; even the circuitry in the chassis can become confusing since related components are often positioned in decentralized areas of the chassis.

In equipment which includes printed circuit boards, identification of circuitry and components may be relatively simple. This type of circuit construction allows uniform placement of components and complete sectionalization of related circuitry. Just a quick, once-over glance of such circuitry is often all that a technician requires to formulate the overall layout of the chassis in his mind and quickly focus his attention on the area of particular concern.

Many of the commercial manufacturers have developed methods of quick identification. One of the most common ways is to impose a grid over a drawing of the board, and then furnish a table which lists the part location. Another technique is to number points of interest on the schematic, then provide a pictorial guide to locate the points on the board.

Circuit tracing of the printed wiring board may be simpler than that of conventional wiring, due to increased uniformity. If the wiring board is translucent, a 60-watt light bulb placed underneath the side being traced will facilitate circuit tracing. Test points can be located in this manner without viewing both sides of the board.

Resistance or continuity measurements of coils, resistors, and some capacitors can be made from the component side of the board. In some cases, a magnifying glass will help in locating very small breaks in the wiring. Voltage measurements can be made on either side of the board. However, a needlepoint probe is needed to penetrate the protective coating on the wiring. Hairline cracks can be located by making continuity checks.

A number of general precautions are necessary when working with modular assemblies. Supervisory personnel should take steps to insure that the technician in their shop or maintenance crew know and understand the rules set forth in the following paragraphs:

1. Observe power supply polarities when measuring the resistance of the circuits of modular assemblies containing transistors, or other semiconductors. Such parts are polarity- and voltage-sensitive. Reversing the plate voltage polarity of a triode vacuum tube will keep the stage from operating, but generally will not injure the tube. However, reversing the voltage applied to a transistor, or other semiconductor, could destroy it very quickly.

Since transistors and similar components require different power supply connections, the personnel who work with these parts must always be alert in connecting test equipment. Make sure that the correct polarity and range are observed. Recheck your work before turning on the power—the wrong polarity will destroy the part.

2. Avoid applying a-c power operated test equipment or soldering iron without first making certain that powerline leakage current is not excessive. It is a good precaution to use an isolation transformer with all test equipment and soldering iron operated on a-c power, unless it has been determined that the equipment contains a transformer in its power supply or shows no current leakage. With all test equipment (whether transformer-operated or not), it is good practice to connect a common ground lead first from the ground of the circuit to be tested, and then to the test equipment ground.

3. Avoid application of too high a pulse from test equipment. The safest procedure is to start with a low output signal setting, and then proceed to apply the required signal levels. Be sure that the signal applied is below the rating given for the circuit under test. Relatively high current transients can occur when test equipment is connected to a circuit where low-impedance paths exist.

4. Avoid moving loose connections, disconnecting parts, inserting or removing transistors or similar components, and changing modular units while the equipment power is on or while the circuit is under test. Moving a loose connection, or any of the actions mentioned, will cause an inductive kickback. This can be prevented by being sure that all parts in the circuit are secure before starting the test or turning on the equipment power. Be sure to remove all possible capacitance charges from parts and test equipment before applying them to a modular assembly. When changing modular assemblies, be sure the equipment power is off.

SPECIAL MAINTENANCE PROBLEMS

The effect of environmental conditions upon the operation of electronic and electrical equipment has greatly increased the maintenance problems of the technician. These conditions may be grouped under the major headings of altitude, temperature, and humidity. At the extremes of these conditions special maintenance and operating procedures are required. Equipments required to function at these extremes frequently fail due to the effect of decreased air density, radical temperature changes, and moisture.

Other special maintenance problems are introduced by the effects of radio noise interference. Among the types of radio noise interference discussed in the following paragraphs are atmospheric interference, effects of rotating and switching devices, effects of nonlinear circuit elements, and interference fr m a-c power sources. Also discussed are methods of suppressing radio noise interference.

HIGH ALTITUDE

As the ceiling for aircraft on extended flights has been raised higher and higher, many new types of operating and maintenance problems have developed. Some of the various types of equipment involved are generators, voltage regulators, electric motors, and solenoids. Electric brushes on generators, inverters, electric motors, and other rotating electrical machinery wear away very rapidly at high altitude. Special brushes have been developed that have longer life at high altitude. Thus, it is advisable to use the proper type brushes and to check them more frequently when high altitude flying is being performed.

While most switches will break a circuit safely at sea level, their contacts may burn and in some cases even melt at high altitude. It has been found that double-break contact switches somewhat alleviate this fault. Since electric and electronic systems use specially designed switches for high altitude operation, it is necessary to take special precautions to insure that the proper type is used by personnel making a replacement.

Other items that often fail during high altitude flights are electrical plugs and receptacles. A voltage breakdown occurs between the pins and shell along the surface of the insulating material. The result is a burned plug. This happens because the breakdown voltage is less at high altitude. For example, the breakdown voltage for a 1/4-inch airgap is about 3.7 times greater at sea level than at 40,000 feet.

This condition may be overcome by sealing the connector with a potting compound. This reduces the probability of arc-over between pins. or between pins and the shell of the electric connector since the dielectric characteristics of the connector are improved. This sealing compound will also protect the connectors from corrosion or contamination by excluding metallic particles, moisture, and aircraft liquids.

Pressurization

Airborne electronic equipment used at high altitudes is usually pressurized for the following reasons.

790 835

1. To prevent high-voltage arcing and resultant wear on brushes and relay contacts.

2. To prevent RF voltage breakdown in waveguides.

3. To eliminate the problems of condensation and corrosion in the equipment which result from "breathing."

Pressurized equipments are sealed with gaskets to make an airtight and moistureproof seal. Pressurization can be accomplished by using a combination dehydrator-hand pump, as is done with the UHF transceiver discussed in chapter 13 of this course. Some equipments have an electric compressor-dehumidifier built in.

The hand pump is used to pressurize some equipments with 18 to 20 psi absolute or 3 to 5 psi gage. Compressors that are installed in the aircraft with equipment such as radar are used to pressurize various units of the system with 30 to 34 psi absolute at all altitudes.

HUMIDITY

Continuous damp, warm air causes condensation of atmospheric moisture within equipment unless units are hermetically sealed or the interiors are maintained at a temperature higher than surrounding atmospheric temperatures. Condensed moisture forms electrical leakage paths and causes corrosion. These climatic conditions also promote rapid fungus growth which in itself has a corrosive effect on materials, such as wire, switch contacts, and other metal parts.

Humidity is a term describing the amount of water vapor in the air. It is usually expressed as a percentage of the total amount of water the air can hold at a given temperature. Thus, 50 percent relative humidity means the air contains one-half the total water it can hold, and 100 percent means it contains all it is capable of holding. Air can hold more water as its temperature increases. In tropical areas the humidity varies between 60 and 100 percent.

High humidity accounts for the condensation of moisture, or sweating, on various parts of electronic equipments when they undergo temperature changes. Condensed moisture on insulating materials reduces their insulating qualities and results in arc-overs and shorts between terminals. The water vapor also penetrates into the body of insulation, is absorbed, and causes similar effects. High humidity also causes corrosion of metals. Other sources of moisture which cause deterioration include fog, salt spray, and rain.

TEMPERATURE

In general, equipment may encounter extreme temperatures, ranging from minus 65° F to a maximum of 135° F, under various climatic conditions of high humidity, fog, rain, salt spray, salt air, cold, insects, fungi, and dust. High temperature and moisture vapor cause rapid corrosion. Fungus and bacterial growths, which thrive in warm temperatures, produce acids and other products which speed corrosion, etching of surfaces, and oxidation. This interferes with the operation of moving parts, screws, and so forth, and causes dust between terminals, capacitor plates, and other parts, which produces noise, loss in sensitivity, and arc-overs.

Variations of temperature cause moisture to be breathed through any small cracks, pinholes, or vents in the equipment. As the temperature rises, the air inside a piece of equipment expands and it is expelled, in part, through the openings and vents. When the temperature falls, the air inside the equipment contracts and outside air is admitted through all openings and vents. The moisture which is breathed destroys the insulating qualities of dielectrics and corrodes metals.

FUNGUS

Fungus is a form of plant life which feeds on materials of vegetable and animal origin including paper, cotton, and so forth, and such things as dead insects and other fungi. These may be spread by wind, dust, dirt, and insects, such as ants, flies, and mites. Growth may take place on materials other than those of organic origin if a spot of dust or other nutrient substance is present.

Fungus growth causes decay, accelerates the deterioration of insulating materials, and short circuits items such as relays, jacks, and keys. The inclusion of a fungicidal compound in the manufacture of the equipment retards the growth of these fungi.

Most new equipment is given a climatic deterioration prevention treatment which provides a reasonable degree of protection against fungus growth, moisture, corrosion, salt spray, insects, cold, desert heat, and so forth. The treatment involves the use of a lacquer or varnish coating material applied with a spray gun or brush. Detailed instructions dealing with this treatment may be found in Climatic

791

Deterioration Prevention Treatment Electronic Test and Communications Equipment, AN-16-1-41.

CORROSION

Modern high speed aircraft are dependent on the operational and structural soundness of metals (basically high strength aluminum alloys) which make up the largest percentage of their thousands of parts. With higher strength demands being made on aircraft metals and the closer tolerances of flight safety which accompany high performance aircraft, these aircraft would rapidly become inoperative without regular anticorrosion maintenance.

In the past, aircraft have remained longer in overhaul activities than was desirable, due to requirements for corrosion removal and surface refinishing. This situation, which adversely affects the Navy's goal of maximum utilization of all available aircraft, has been the subject of much discussion by persons responsible for aircraft maintenance policy. The results of these studies have pointed out the need for ever-increasing emphasis on corrosion control at all maintenance levels. The senior technician may be attached to a unit which has a fully developed corrosion control program in operation and in this case he need only familiarize himself with the program and with his responsibilities in making the program a successful venture.

If no corrosion control program exists on squadron or department level, the senior technician should give consideration to establishing such a program on a shop, division, or other level where his supervisory reponsibilities lie. This course will point out briefly some of the dangers of corrosion and will list some of the information sources to which the senior technician can refer for detailed information on corrosion control.

Corrosion can cause eventual structural failure if left unchecked. The appearance of the corrosion differs with the particular metal involved. On aluminum alloys and magnesium it will appear as surface pitting and etching, often combined with a gray or white powdery deposit. On copper and copper alloys, corrosion forms a greenish film; on steel a reddish rust.

When the gray, white, green, or red deposits are removed, each of the surfaces may appear etched or pitted, depending upon the length of exposure and the severity of the attack. If these surface pits are not too deep, they may not significantly alter the strength or ductility of the metal; however, even here the pits may become sites for crack development on parts which are critical stress members. Some types of corrosion can travel beneath the surface coatings and can spread undetected until they perforate the coating or the part fails.

A thorough comprehension of the dangers of corrosion, the ability to recognize the various types of corrosion, and the development of the skills necessary to cope with them should be included in the objectives of the training program. The technician will find that aircraft corrosion control aboard ship frequently turns out to be an all-hands evolution. In his day to day work he can improve the quality of corrosion control by observing precautions and initiating proper maintenance procedures.

Water and spray containing salt combine with oxygen in the atmosphere to form the main source of corrosion in aircraft. Therefore, naval aircraft operating in a marine environment are particularly susceptible to corrosive attacks. The corrosion problem for the technician is compounded when one considers that many equipments have components which are mounted in positions which can act as traps for salt spray or sea water vapor.

The senior technician should be familiar with publications which contain valuable information concerning corrosion control. In addition to local directives on this subject the technician will find that complete technical information for specific application may be obtained from the following:

1. Corrosion Control for Aircraft, NavWeps 01-1A-509.

2. Aircraft Maintenance Cleaning Manual, NavWeps 01-1A-506.

3. Preservation of Naval Aircraft, NavWeps 15-01-500.

In addition to the formal manuals listed above, the supervisor will find information on this subject in various manufacturer's instructions furnished with equipments. Another source available to the supervisor when searching for information on this subject, or almost any subject relevant to electronics, is the Digest of Naval Aviation Electronics (NAESU Digest), NavAir 08-1-503.

RADIO NOISE INTERFERENCE

Radio noise interference is a problem of first importance to maintenance personnel. The problem has increased in proportion to the complexity of both the electric system and the electronic equipment. Almost every component of the aircraft is a possible source of radio interference, which is one of the main factors in preventing the operation of receivers at full sensitivity. All personnel concerned should be familiar with the problem of radio noise and how to eliminate it.

The overall effect of radio interference of any kind is to impair or deteriorate the performance and reliability of radio and electronic sets or systems. The interference may act directly by actual deterioration of the equipment response, or indirectly by wearing down the patience and tolerance of the human operator. Either way, the result is the same, since combat efficiency is materially reduced.

The technician should know the following:

1. What radio interference is.
2. Where the interference originates.
3. How it gets into equipment.
4. How to identify it.
5. How to suppress it at its source.
6. How to segregate its path of entry into a receiver
7. How to prevent its entry into a receiver.
8. What considerations enter into the design of an interference-free equipment.
9. How to position and install electrical and electronic devices.

This information is presented in detail in the publication, Installation and Maintenance Practices for Reduction of Radio Interference in Aircraft Electronics, NavAer 16-1-521. Some of the more important of this information is presented briefly in the following pages.

Atmospheric and Precipitation Static

Atmospheric static is a burst of RF energy caused by electrical discharges in the atmosphere. Although the frequency spectrum of atmospheric static is very wide, only frequencies in and below the high frequency band propagate far enough to be very troublesome at long distances from the electrical disturbance. Therefore, UHF and VHF receivers are seldom troubled by atmospheric static. Reduction of such static is obtained by use of frequency modulation, directional antennas, and noise limiter circuits. Frequency modulation is not used extensively in aircraft radio communications because of the bandwidth requirements.

Precipitation static is caused by the development of large static charges on the aircraft when it is flown through snow, rain, ice crystals, or dust clouds. An aircraft can build up a charge of several hundred thousand volts in a few seconds. The resulting high voltage gradients at extremities and sharp points exceed the breakdown strength of air and cause noisy corona discharges.

The conventional radio antenna, which must stand away from the body of the aircraft to be of effective height, is exposed to high electric fields. This means that corona discharges occur first in the antenna system, the very place that is most sensitive to noise. Precipitation static is reduced by using a completely insulated antenna system—that is, by using wire with high voltage insulation instead of bare wire, and by insulating all connections and supports for the antenna wire.

Precipitation static is reduced also by eliminating all sharp metal projections from the aircraft and by installing dischargers, which quietly discharge accumulated static charges at a high rate. A discharger consists of silver-impregnated cotton wicking encased in a flexible plastic tube with an aluminum mounting lug. The many fine high resistance fibers provide a multitude of discharge points. The resulting discharges are quiet unless the current is very high. For detailed information on precipitation static refer to NavAer 16-1-518, Installation and Maintenance Instructions, Anti-Precipitation Static System.

The effect of precipitation static is a loud hissing or frying noise from the speaker or headset of radio equipment and interference (grass) on the picture tube of visual output receivers. As a technician you should be concerned with precipitation static since it is produced only when the aircraft is flying. Also, the preventive measures that are taken are among the primary responsibilities of your rating. You should be aware of its characteristics for there is the probability that you will have to correct for radio interference that is caused by precipitation static.

Manmade Radio Noise

Manmade radio noise is caused by electrical transients which occur during the operation of electrical or electronic equipment. In brief, manmade radio noise will be generated whenever an electrical circuit is open or closed abruptly, such as by a relay, commutator, or other make and break devices. A similar condition exists when large amounts of current are periodically and abruptly started and stopped, as in radar circuits. An electric spark is a generator of electrical disturbances which appear to cover the entire radiofrequency spectrum.

ROTATING ELECTRIC MACHINES.—The types of interfering voltages generated by d-c machines are:

1. Switching transients as the brush moves from one commutator bar to another. This is usually called commutation interference.
2. Random transients caused by varying contact between brush and commutator. This is usually called sliding contact interference.
3. Audiofrequency hum (commutator ripple).
4. Radiofrequency and static charges built up on the shaft and rotor assembly.

Direct-current motors used in aircraft systems are of three general types: series wound, shunt wound, and permanent magnet field. The field windings of both series- and shunt-wound motors afford some "padding" or filter action against transient voltages generated by the brushes. The permanent-magnet motor's lack of such inherent filtering makes it a very common source of interference.

It must be emphasized that the size of a d-c motor has little effect upon its interference generating characteristics. The smallest motor aboard may well be the worse offender.

The output of an ideal a-c generator is a pure sine wave. A pure sine wave voltage is incapable of producing interference except at its basic frequency. However the ideal waveform is difficult to produce, especially in small machines.

Practically all types of a-c power generators currently used in naval aircraft have proved to be potential sources of interference at other than the output power frequencies. This interference is produced in the following forms:

1. Harmonics of the power frequency, caused by poor waveform.
2. Commutation interference (series-wound motors).
3. Sliding contact interferences (a-c generators and series-wound motors).

It should be noted that a-c motors that do not use brushes are almost never sources of interference.

SWITCHING DEVICES.—Abrupt changes in electric circuits occur when switching takes place. Such changes are accompanied by transients capable of interfering with the operation of radio and electronic systems. The simple manual switch is of little consequence as a source of interference because its frequency of operation is usually not great. Example of frequently operated switching devices capable of appreciable or serious interference are relays, vibrators, and thyratrons.

Since relays are used almost exclusively to control large amounts of power with relatively small amounts of power, they are always potential interference sources. This is especially true when they are used to control inductive circuits. Relay actuating circuits should not be overlooked as interference sources, because even though the actuating currents are small, the inductances of the actuating coils are usually quite high. It is not unusual for the control circuit of a relay to produce more interference than the circuit which it controls.

Induction vibrators are essentially double-pole, double-throw relays which operate at a constant rate. As in any induction type switch or relay, there are two sources of switching transients: the inductive field contacts and the switching contacts. The output waveform of the vibrator is essentially rectangular at some audiofrequency. Its harmonic content is high and filtering is difficult.

Because of its interfering capabilities, the vibrator is seldom used as a radiopower source in naval aircraft except for certain commercially available radio equipments found in small auxiliary aircraft. (Vibrators are used as d-c choppers in some servosystems.)

Thyratrons are gas filled, grid controlled, electronic switching tubes which are used for many purposes. Among the most common uses are keyer tubes in radar modulators, rectifiers in regulated power supplies, rectifiers in servosystems, and relay applications. The current flow in a thyratron is either all on or all off; there is no in-between. Since the time required to turn a thyratron on is only a few microseconds or less, current waveforms in

794

thyratron circuits always have steep fronts. As a result, they are rich in radio interference energy (transients).

NONLINEAR CIRCUIT ELEMENTS.—A conductor or semiconductor whose resistance or impedance varies with the voltage applied across it is a nonlinear element. Nonlinear elements that may cause radio interference in aircraft, in the order of their frequence, are overdriven vacuum tubes, oxidized or corroded joints, cold solder joints, and unsound welds. In the presence of strong signals a nonlinear element behaves as a detector or mixer, producing harmonics and sum and difference frequencies from signals applied to it.

A-C POWER SOURCES.—Radio interference of a broadband nature is produced by a-c power sources. In a-c powered equipments, a-c hum may appear at the power frequency or at the rectification ripple frequency. The ripple frequency of a full-wave rectifier is twice the power frequency times the number of phases. Normally, aircraft systems utilize only single- and 3-phase sources at 400 cps. Full-wave rectification of single-phase, 400-cps power gives a ripple frequency of 800 cps; a 3-phase source yields 2,400 cps. This ripple can produce interference varying from annoyance to complete unreliability of equipment, depending on its severity and its coupling to susceptible elements.

SUPPRESSION METHODS.—Suppression of radio noise has advanced to the point where the proper application of available techniques will insure that receiving equipment installed in aircraft will operate at optimum efficiency. Four types of suppression techniques are involved.

Isolation is the easiest and most practical method of radio noise suppression and revolves around the possibility of separating the source of radio noise from the input circuits of the receiving equipments affected. As every man-made radio noise source can be considered a small transmitter, it is obvious that the radio noise source and leads carrying radio noise energy should be kept as far away from receiver antennas or lead-ins as possible.

In many cases, the radio noise in a receiver may be entirely eliminated simply by moving the antenna lead-in wire just a few inches away from the source of radio noise. The value of sufficient separation between sources of radio noise and receiver input circuits is not apt to be overemphasized. The isolation method of radio noise suppression is very popular as it has the advantages of not requiring any additional material or adding any additional weight.

Bonding is a very important means of radio noise control. It provides grounding of all insulated conducting objects on the exterior of the aircraft. When conducting objects are not grounded, flight through precipitation causes high voltage charges to build up on those objects. Repeatedly, the voltage gets high enough to spark over to an adjacent ground member or the object discharges to the surrounding air by corona conduction. Either mode of discharge causes considerable radio noise.

Other important functions of bonding are:

1. To protect the aircraft and personnel from lightning discharges by equalization of potentials which might cause arcs and sparks in the aircraft structure.
2. To provide a homogeneous counterpoise for radio transmission and reception.
3. To provide power current return paths.
4. To provide a short path bypassing RF noise.

All electronic equipments should be ground to the aircraft structure. This is done by using short bond straps or sheets of high conductivity (copper or aluminum) metal where it is impossible to use a short bond strap. No bond strap should be more than 4 inches in length.

Shielding is one of the most effective methods of suppressing radio noise. The primary object in shielding is to electrically "bottle up" the radiofrequency noise energy. In practical application, this means that the radio noise energy must be kept flowing along the inner surface of the shield. The use of good shielding is particularly effective in situations where filters cannot be used. A good example of this is where radio noise energy radiates from a radio noise source and the radiated energy is picked up by the various circuits that eventually connect to the receiver input circuits. It is obvious that it would be impractical to filter a number of leads or units that are influenced by the radio noise energy; hence, the application of effective shielding at the noise source itself is advisable for it will eliminate the radiated portion of the radio noise energy by confining it within the shield at its source.

Radio interference as radiated or conducted from a source may be of a single frequency or may cover an extended band of frequencies. When bonding, shielding, or isolation of the source proves ineffective as a means of reducing radio interference, it becomes necessary

795 [illegible]

to employ filters to accomplish this reduction. A filter is defined as a selective network which transmits freely electric waves having frequencies within one or more frequency bands and which attenuates substantially electric waves having other frequencies.

The size of a filter may vary widely, depending on the voltage and current requirements as well as the degree of attenuation desired. Filters are usually incorporated in equipment known to generate radio interference, but these filters are often inadequate, and in many cases it is necessary to add filters external to these equipments. This is especially true if the source of interference is coupling interference to paths of entry to a receiver other than the powerline.

The types of filters used in the reduction of radio interference vary with the application, but each of the general filter types may be found to be particularly adaptable to some specific situation. Most of the electrical devices connected to powerlines require, for their operation, features which are conductive to the generation of radio interference.

The interference generated by these devices, unless properly attentuated, is impressed upon the power lines and conducted to the receivers. It may also be conducted into the receivers by inductive coupling to other wiring associated with the receivers. This interference, unless attenuated by means of filters, is then transmitted along these powerlines, entering the receivers at the powerline input; or this interference may be radiated somewhere along the powerlines and enter the receiver by means of the antenna system.

Filters are of four kinds and are identified as follows:

1. The low pass filter, which introduces negligible attenuation at all frequencies below a certain frequency, called the cutoff frequency, and relatively high attenuation at all higher frequencies.

2. The high pass filter, which introduces negligible attenuation at all frequencies above a certain frequency, called the cutoff frequency, and relatively high attenuation at all lower frequencies.

3. The bandpass filter, which introduces negligible attenuation at all frequencies within the range between two frequencies, and relatively high attenuation at all other frequencies.

4. The band elimination filter, which introduces negligible attenuation at all frequencies outside a certain range, and relatively high attenuation at all frequencies inside that range.

For information that covers the theory of operation of these filters, refer to chapter 4 of Basic Electronics, NavPers 10087-B.

The normal characteristics of a filter are obtained only when the filter is properly terminated in its characteristic impedance.

A wave trap is a filter or network especially designed to reject certain frequencies, or bands of frequencies. Networks of this type may be installed at the antenna of the transmitter or receiver in order to attenuate frequencies outside of the assigned frequency range of the equipment. All such networks must have low insertion loss, or attenuation, for the pass frequencies. In the design and construction of wave traps, the insertion loss is usually below 2 db.

There are two basic circuit configurations for filter networks, the pi-section and the T-section. Each may be broken down into half section which have an inverted L-shape and are known as L-section filters. If a number of pi- or T-sections are connected in series to form a filter, the resultant network is called a ladder network. Any of the above circuit configurations may be used for radio interference elimination.

In general, the use of simple capacitor filters is to be preferred over that of the more complicated network filters in cases where this type of filter provides the required degree of radio interference attenuation. In this method, the radio noise energy passes through the capacitor to ground. This sort-circuiting effect is due to the fact that the capacitor offers a very low impedance path across the noise source terminals.

A given capacitor is effective in bypassing only a limited range of radio interference frequencies because of its internal inductance and the inductance of the connecting leads. The inductance of the capacitor depends upon its capacity, the material of which it is fabricated, and the length of the connecting leads.

The capacitor leads are the major contributors to the inductance of capacitors. Therefore, small mica capacitors, with short leads are more effective as filters at high frequencies than large paper capacitors with normally long leads. Electrolytic capacitors should never be used as filters because of the danger of dielectric breakdown.

The popularity of the capacitor type filter is due to the fact that the current used for operation of the radio noise source does not have to pass through the filter. The only energy passing through the filter is the radio noise energy. The most important limiting factor in the choice of a capacitor type filter is the breakdown voltage rating of the capacitor. It must be well above the voltage used to operate the source of radio noise to be filtered. For example, where a 24-volt source of noise is to be bypassed with a capacitor, the working voltage of the capacitor should be at least 50 volts.

CHAPTER 7

TEST EQUIPMENT

For effective operation of an avionics system, it is imperative that the electronic equipments operate at maximum effectiveness within the designed limits. To accomplish this, the technician must employ the best maintenance techniques and he must utilize the test equipment to the utmost.

The following discussion on the operation and circuitry of various test equipments is designed to aid the AT in furthering his knowledge of these test equipments and their use in effective maintenance of avionics equipments. The technician should bear in mind that this discussion is not a substitute for the test equipment's Operation Instruction or Service Instruction Manual, which should be consulted before operating any type of test equipment.

OSCILLOSCOPE

Oscilloscope AN/USM-140A, which is discussed in the following paragraphs, is a high speed precision instrument utilizing plug-in units for maximum accessibility and flexibility. The vertical deflection amplifier bandpass is designed for operation from d. c. to 30 mc, and the temperature range is from minus 28°C to plus 50°C. The sweep generator which is part of the horizontal deflection system provides a variable range of sweep times. This range is from 0.1 μ sec per cm to 5 sec per cm.

FUNCTIONAL DESCRIPTION

The functions of the AN/USM-140A may be divided into six major sections. Each section is vital to the purpose of the instrument, which is the production of transient and graphic displays of electrical waveshapes on the face of a cathode-ray tube. Figure 7-1 shows the six major sections, with dotted lines to indicate d-c voltage distribution. The solid arrows show signal paths. The calibrator is not shown in the block diagram because it is a convenience, not vital to the functions of the oscilloscope.

The preamplifier receives the vertical signals and provides the required amplification. It then applies those signals (individually, alternately, or chopped) to the main vertical amplifier. To do this, an electronic switch is provided as a part of the plug-in unit.

The main vertical amplifier is a wideband circuit which raises preamplifier input signal voltage to deflection plate requirements. It provides impedance matching for the preamplifier and for the CRT deflection plates, with frequency compensation to well above 30 mc. Some of the signal is applied to the sweep generator for internal triggering. The large output of the main vertical amplifier drives the CRT deflection plates.

The sweep generator is the source of sawtooth horizontal deflection voltages for the CRT. Highly linear waveforms are available over a wide range of frequencies and they are calibrated in time. Sweep signals may be triggered by the vertical signal, internal or external a-c sources, or by external d. c. Free-running sweep may be used if desired. Additional controls are provided by plug-in units.

The horizontal amplifier has two inputs; it may receive sweep generator output, or it may receive external sweep voltages through the input jack. It amplifies these low-level signals and applies them to CRT deflection plates in push-pull circuitry.

The low voltage power supply provides all a-c and d-c voltage requirements for the oscilloscope from the a-c power line. Solid state rectifiers and voltage regulators are used throughout. Except for filament and fan supplies, all voltages are regulated. Five fuses protect the power supply; a sixth fuse protects the fan and d-c filament supply.

798

ter

Figure 7-1. —Oscilloscope block diagram.

The high voltage power supply provides all the accelerating anode and focus voltages for the CRT. It also provides matrix circuitry for blanking and unblanking voltages, alternate switching signals, and intensity modulation.

MAIN VERTICAL AMPLIFIER

The main vertical amplifier comprises two identical d-c amplifiers, arranged for balanced push-pull operation. Figure 7-2 shows a block diagram of those circuits. The cathode follower stages provide good impedance transformation and circuit isolation between stages. The trigger sample is taken off after the second cathode follower and ahead of the delay line. A 0.20-μsec delay is included so that trigger signals may start the sweep before the vertical signal is applied to the CRT. The high frequency response is adjusted in the cathode follower driver output. The output amplifier stage has four dual triodes connected in push-pull-parallel for good driving power with low noise factor. One section of the BEAM FINDER switch limits the gain of the output stage to limit deflection.

Sweep Generator

The sweep generator is shown in block diagram form in figure 7-3. The heart of this unit is the gate generator. It produces a square wave gate signal which is then integrated to form a sawtooth sweep voltage. Cathode followers provide power output and generator isolation to four outputs. Stop and start of the gate generator is controlled by bias control and trigger signal.

Trigger Amplifier and Generator

The trigger signal, selected at the TRIGGER SOURCE switch, is applied to the TRIGGER SLOPE switch. From there, the signal enters the trigger amplifier V101, according to polarity selected. The amplified signal is then applied to a Schmitt trigger circuit, V103. This circuit, discussed in more detail later in this chapter, is a bistable multivibrator which produces spike pulses precisely timed by the trigger signal. The voltage spikes are added to the d-c level from the bias controls (V113A and B) and this composite voltage is then applied to the gate generators (V104 and V105A).

799 808

Figure 7-2. —Main vertical amplifier block diagram.

The threshold sensitivity of the trigger amplifier is set by bias from the TRIGGER LEVEL control. This limits the minimum trigger voltage and permits lower noise voltages to be eliminated. Since it also affects the gain of V101, it governs the amplitude of the trigger voltage at the V103 input. Thus it affects triggering sensitivity. The TRIGGER SLOPE switch permits phase inversion in V101A for positive-going signals. For negative-going signals, it uses V101B to apply cathode drive to V101A, eliminating phase inversions. The TRIGGER SLOPE switch thus determines whether the sweep starts on negative or positive triggers.

GATE AND INTEGRATOR CIRCUITS

The gate generator is a Schmitt trigger, designed for square wave output in bistable operation. Tube V113 holds gate bias near a critical firing point between sweeps. In this condition, V104A is on (saturated conduction) and V105A is off (nonconducting). Diode switch CR104 is held on by positive gate voltage of V105A, clamping the integrator input. No sweep occurs in this phase.

Trigger generator V103 produces reduced positive and large negative pulses. The positive pulses have no effect, but the first negative pulse causes the gate to switch, turning V104A off and V105A on. The large negative gate voltage at V105A opens the diode switch CR104, freeing the integrator input. Simultaneously, the gate generator supplies positive gate voltage for cathode follower outputs. With the integrator input free, the sweep capacitor charges and the integrator amplifies this signal, producing a positive voltage ramp for sweep output. Ramp signal feedback affects sweep capacitor charging to produce a highly linear sweep signal.

Sweep feedback through V114A and V113B triggers V104A on, resetting the gate and ending gate pulses. Positive gate to CR104 again turns on the diode switch. Clamp V105B then discharges the sweep capacitor, and the integrator amplifies this retrace voltage. Clamp action assures that all sweeps start at the same level, about -50 volts. Capacitive action in the holdoff circuit prevents retrace overshoot which might trigger the gate prematurely, before other circuits has stabilized. Note that the SWEEP TIME switch changes the sweep resistor and capacitor and the holdoff capacitor.

SCHMITT TRIGGER CIRCUIT

A Schmitt trigger is a form of bistable, cathode coupled multivibrator. Figure 7-4 is a simplified schematic of a Schmitt circuit with corresponding waveforms. Tubes V1 and V2 operate alternately so that V2 is conducting when V1 is cut off, and vice versa. As input to V1 becomes more positive, it reaches the predetermined level A of figure 7-4 (B). Then the trigger flips, V1 starts conducting, and V2 is cut off. When the input voltage begins to go negative, the grid of V2 becomes more positive. When it reaches the second predetermined level B of figure 7-4 (B), V2 once again conducts and

Figure 7-3. —Sweep generator block diagram.

V1 is cut off. Figure 7-4 (B) shows the relationship between the input and output of the Schmitt circuit. Points A and B are the voltage limits at which the trigger switches. The output of V2 is a square wave. Notice that the trigger will not switch unless the input signal is

Figure 7-4. —Schmitt trigger circuit. (A) Simplified schematic; (B) waveforms.

large enough to cross both the upper and the lower limit.

SINGLE SWEEP OPERATION

For single sweep operation, the gate generator bias is held well above trigger level by V113B (fig. 7-3). To do this, V113 is converted to a Schmitt trigger by the SWEEP OCCURRENCE switch in the SINGLE position. Sweep feedback controls the trigger after each sweep, setting it with V113A on and V113B off. A positive pulse is then applied to reverse the trigger so that V113A is off and V113B is on. This arms the gate according to SWEEP MODE bias selection. Thus the gate is in readiness for trigger and can fire just once.

HORIZONTAL AMPLIFIER

Figure 7-5 shows a block diagram of the horizontal amplifier. Although the HORIZONTAL DISPLAY switch is simplified in this drawing, it governs the input of V201A and the gain of the horizontal amplifier. Cathode follower V201A may receive input from the sweep generator or it may take external input through cathode follower V201B. Output from V201A drives the grid of V202A, which in turn drives the cathode of V202B. Transistors Q201 and Q202 form a balanced differential amplifier with transistor driver stage V202, providing a balanced drive to cathode followers V206A and B. Power output from V206A and B drives CRT deflection plates and capacitance driver V207. Action of V207 improves the high frequency deflection waveform by effectively reducing capacitive reactance of the deflection plates. The plate resistance of V207 is effectively in parallel with deflection plate capacity. Its plate current is adjusted for leading phase, aiding during deflection plate capacity charge.

LOW VOLTAGE SUPPLIES

Figure 7-6 shows a block diagram of the low voltage power supplies. All are voltage regulated with exception of the fan and a-c filament supplies. The -100 volt supply is the reference standard and takes its reference voltage from a voltage regulator tube. The other power units are dependent on the reference voltage of the -100 volt supply. The rectifiers are bridge circuits except for the 6.3-volt unit which is a simple full wave rectifier. Transistorized voltage regulators maintain average ripple output to 6 mv/100 volts. The series regulator transistors are mounted in heat sinks in the fan shroud. Each d-c supply is protected by individual fuses, and the power transformer is protected by both line fuses and a thermal breaker. Each power supply may be manually set to the desired output voltage.

The voltage regulators follow conventional regulator operating theory. Briefly, the series regulators produce a variable voltage drop, under control of the differential amplifiers. To produce this control, the amplifiers compare output voltage to the standard -100 volt supply. Any change in output voltage is sensed and counteracted by those amplifiers. A drop in output voltage is offset by a reduced voltage drop across the series regulators. If output voltage starts to rise, an increased voltage drop occurs across the series regulators.

Figure 7-5. —Horizontal amplifier, block diagram.

HIGH VOLTAGE SUPPLIES

Figure 7-7 shows a block diagram of the high voltage supply for the CRT. V304 and the primary of the high voltage transformer form a Hartley oscillator. The 50-kc output in the primary is stepped up in the secondary windings to supply the rectifiers with high voltage

Figure 7-6.—Regulated power supply block diagram.

803

a.c. V310 and V311 are simple half-wave rectifiers which supply intermediate high voltage d.c. to the cathode and grid of the CRT. V307, V308, and V309 form a voltage tripler which provides high voltage d.c. for the CRT anode. Variations in d-c output of V310 are fed back to amplifier V301. Amplifier output controls screen voltage of V304 to offset the variation, providing voltage regulation of d-c output to the cathode of the CRT.

VOLTAGE TRIPLER OPERATION

Simplified schematics of the tripler are presented in figure 7-8 to show capacitor charging steps. Tubes V307, V308, and V309 are shown as switches, with arrows to indicate electron flow. Figure 7-8 (A) shows the condition on the first half-cycle of transformer a.c. where E indicates transformer peak voltage. Capacitor C311 charges during this interval to 1E. In the next half-cycle, figure 7-8 (B), C309 charges to 2E due to transformer voltage added to that of C311. In figure 7-8 (C), the next half-cycle again charges C311, and polarity is such that V307 conducts, charging C310 to 2E. Since the voltage of C310 is 2E and that of C311 is 1E, the output voltage is 3E, or approximately three times transformer peak voltage.

The brightness of the trace is adjusted by the INTENSITY control, varying the d-c grid bias of the CRT. Cathode voltage is held constant from V310, while negative voltage to the grid is varied. Bias is usually set just below cutoff, allowing positive gate pulses to unblank the CRT in step with the sweep. Gate and sweep times are identical and the CRT remains on during internal or external sweeps. A section of the BEAM FINDER switches an additional -100 volts in the cathode supply to reduce CRT bias and produce a brighter trace. The ASTIGMATISM control corrects defocusing errors produced by deflection of the beam. It does this by varying the CRT screen voltage, effectively changing the shape of beam apertures within the CRT.

Figure 7-7. —High voltage power supply block diagram.

Figure 7-8. —Voltage tripler.

CALIBRATOR

The calibrator consists of a plate and cathode coupled multivibrator with a free-running frequency of 1 kc. Its output is clipped on positive and negative peaks at zero and +110 volts. The square waves produced are applied to an attenuator for pulse output calibrated in millivolts and volts. A calibrated 5-ma current output is available between the volt and millivolt jacks when the CALIBRATOR switch is set to CURRENT. No adjustments are required in this circuit.

MAINTENANCE

Maintenance of the AN/USM-140A oscilloscope does not require special procedures. Test equipment maintenance of a general nature is covered in the last section of this chapter.

TACAN BEACON SIMULATOR

This equipment is a test set designed to produce simulated TACAN surface beacon signals and other signals for testing airborne TACAN equipment.

The TACAN Beacon Simulator, Radio Test Set AN/ARM-22, can simulate fixed or variable ranges from 0 to 198 miles, all bearings from 0° to 360°, and tone signals for the operation of the identity circuits of the airborne receiver-transmitter. The test set can transmit these simulated signals to the equipment being tested on any one of 126 preselected channels.

When used in conjunction with Test Set Indicator AN/ARM-31, the capabilities of the equipment are increased. The simulator information sent to, and then processed by, the equipment being tested may be displayed by the test set indicator. This enables the operator to test individual components of the aircraft TACAN equipment.

The AN/ARM-22 is usable at shore station maintenance facilities as well as aboard ship.

OPERATING PROCEDURES

The Operation Instruction Manual, NavAer 16-30ARM-22-501, is supplied for use with Radio Test Set AN/ARM-22. Instructions contained in this manual should be followed when operating the test set.

In addition to the step by step operating instructions, the manual contains operating checks and adjustments, operating precautions, listings of equipment furnished and equipment needed, and general information on the AN/ARM-22.

THEORY OF OPERATION

This section covers the theory of operation for Radio Test Set AN/ARM-22. A discussion of the TACAN system and surface beacon is included to familiarize the maintenance technician with the overall system tie-in.

TACAN System

The test set provides simulated TACAN surface beacon facilities for conducting preflight tests of airborne TACAN receiver-transmitters.

These tests are carried out under closed circuit conditions and provide artificial range, azimuth, and tone identify information for performance evaluation of the associated circuitry in the airborne equipment.

The surface beacon provides a composite envelope which consists entirely of pulse pairs that are generated at the rate of 3,600 pairs per second. Of these pulse pairs, 900 are repetitive reference groups. The remaining 2,700 pulse pairs constitute fill-in "squitter" (randomly occurring pulses) and reply pulse pairs. used for distance information. In conjunction with the 900 reference group pulse pairs, all pulse pairs are amplitude modulated by the beacon antenna rotation, at 15 and 135 cps, for azimuth information.

To obtain distance information, the aircraft transmitter radiates a series of interrogation pulse pairs. These pulse pairs are picked up by the receiver portion of the surface beacon and, following a fixed delay of 50μ sec, retransmitted to the aircraft as an identical series of reply pulse pairs. The time interval between interrogation signal transmission, beacon reply, and pulse reception by the receiver portion of the aircraft equipment, is a function of the distance between the aircraft and the beacon. This interval is directly translated into terms of distance and is displayed on a suitable indicator in the aircraft. Other aircraft, which use the same surface beacon, employ the same operating frequency. However, the pulse repetition frequency (PRF) of the interrogating signal has random pulse spacing and is different for each aircraft. The beacon transmitter replies with a PRF identical to those transmitted and the aircraft receiver circuits ignore PRF's which are not identical to those originally transmitted. This method permits the simultaneous use of the same beacon by as many as 100 aircraft.

Azimuth information is transmitted by amplitude modulation at 15 and 135 cps. It is necessary, therefore, to insure that in the absence of sufficient interrogation, the pulse output is maintained at an average of 2,700 pulse pairs per second plus the reference pulse groups which preserve the complete modulation envelope. This is done by supplementing the interrogating pulse pairs by sufficient squitter pulse pairs. When interrogation pulse pairs are received, a sufficient number of squitter pulses will be eliminated to keep the rate constant at 2,700 pulse pairs per second.

The beacon antenna has an omnidirectional radiation characteristic modified by a rotating parasitic reflecting element. This produces a rotating cardioid pattern which sinusoidally modulates the beacon transmitter pulse pair output with respect to any one reception position. The frequency of this modulation is 15 cps. The positive going crossover point of this modulation occurs when received from a position due south of the beacon. At this time, a north reference burst is radiated by the beacon transmitter. The relative phase difference between this reference group and the 15-cps sinusoidal modulation waveform is translated by the airborne receiver circuits into terms of bearing information for display by an instrument in the aircraft.

To increase the accuracy of the bearing information, the RF pulse output from the beacon antenna is also modulated at a frequency of 135 cps by the use of nine additional parasitic reflectors. The reflectors introduce a superimposed 135-cps sine wave component on the 15-cps cardioid pattern. Corresponding auxiliary reference bursts are provided in the transmitter output. They are phased so that the positive going crossover point of the 135-cps modulation will coincide with the 135-cps reference burst, with respect to a reception position due south of the beacon. The 135-cps reference bursts and complete cycles of 135-cps modulation repeat at angular intervals of 40°, with respect to the rotary 15-cps cardioid pattern. This improves the accuracy of the obtained bearing.

For purposes of beacon identification, the random squitter pulses are periodically replaced at 740μ sec intervals by pulse pairs spaced 100μ sec apart. These evenly spaced groups form a 1,350-cps tone which is phase locked to the auxiliary bursts and keyed with the beacon identification signal in Morse code.

Radio Test Set AN/ARM-22

Radio Test Set AN/ARM-22 provides range and bearing signals, identical to those of the surface beacon except for tone coding, for preflight testing of airborne TACAN equipment. The test set consists of the following four major units:

1. Range and Azimuth Simulator SM-142/ARM-22.
2. Pulse Generator SG-317/ARM-22.
3. Signal Generator SG-318/ARM-22.
4. Power Supply PP-2110/ARM-22.

A functional block diagram of the test set is shown in figure 7-9.

808

Figure 7-9. —AN/ARM-22 functional block diagram.

The power supply provides regulated voltages for the range and azimuth simulator and the pulse generator. The signal generator contains its own power supply circuitry.

The range and azimuth simulator simulates range and bearing information and uncoded tone pulses for the identity tone signal. Bearing information consists of a north reference trigger, auxiliary reference triggers, and 15-cps and 135-cps variable phase sine waves. Range information consists of suitably delayed range reply triggers.

The range, bearing, and tone information developed in the range and azimuth simulator is supplied to the pulse generator. The pulse generator circuits develop the correct spacing between pulses of groups, code and shape the output pulses, generate squitter signals, and modulate the pulse output at 15 and 135 cps. Controls are provided so that range and bearing signals may be made available individually, or combined with squitter signals. The output of the pulse generator, which consists of signals selected by the operator, is then applied to the signal generator. The pulse generator circuits also supply square pulses to the signal generator. These square pulses are synchronized with the shaped video pulses. The square pulse train is identical to the shaped pulse train but is not sine wave modulated. These pulses key the RF generating stages in the signal generator prior to modulation by the pulses.

The signal generator generates crystal controlled RF signals for each of the 126 channels. Channels 1 through 63 operate in a frequency range from 962 through 1,024 mc; channels 64 through 126 operate in a frequency range from 1,151 through 1,213 mc. The desired composite video signals from the pulse generator are applied to the signal generator where they are used to modulate RF signals. The signals may be amplitude controlled and applied to the airborne receiver-transmitter under test. When the function selector switch is placed in the PULSE OUT position, the signal generator output is in the form of pulse modulated RF power, thus simulating the beacon output in space. A CW RF output signal is obtained when the function selector switch is placed in the CW OUT position.

POWER SUPPLY. —The power supply unit, shown in block diagram form in figure 7-10, furnishes regulated d-c voltages at +250v,

807 808

Figure 7-10. —Power supply, block diagram.

+150v, and -120v, and an unregulated d-c voltage at +28v to the range and azimuth unit and the pulse generator.

Primary a-c power is supplied through jack J1. With the a-c power switch S1 in the OFF position, power is supplied to the standby heaters in the three units. When S1 is energized, the heaters are cut off and power is applied to blower B1 and to three separate power supplies. Each power supply employs standard rectifier and filter circuits and a series regulated output circuit, which is controlled by a gas filled reference tube and a control tube.

Relay K1 protects circuits in the range-azimuth and pulse generator units by preventing application of plate voltages until the bias supply is operating. Controls and monitoring jacks on the front panel permit adjustment of each of the regulated voltages.

Primary d-c power at 28v is supplied through jack J2 and controlled by switch S2.

All power outputs are available at the power output jacks. Each input power line and power supply is separately fused by front panel fuses.

RANGE AND AZIMUTH UNIT. —The range and azimuth unit (fig. 7-11 and fig. 7-12) provides appropriately delayed range reply trigger pulses, north and auxiliary reference burst triggers, simulated bearing signals, 1,350-cps tone triggers, and a 4,046-cps test signal.

Range interrogation pulse pairs from the radio set under test are decoded in the signal generator and fed to the simulated range reply circuits. The range decoder circuit decodes range interrogation pulse pairs into a single pulse delayed about 11 μ sec. Each of these

Figure 7-11.—Range and azimuth unit, bearing and tone circuits, block diagram.

pulses is used by the pulse train generator circuit to produce a pulse train 3,000 sec long, with individual pulses spaced at 222.2-μsec intervals corresponding to 18-mile separation between pulses. A five-position switch selects the mode of operation of the range reply circuits by selecting the proper range selector circuit.

The variable range rate circuit utilizes a motor driven potentiometer to produce a range sweep at a predetermined rate. Each range sweep covers fixed limits, according to the setting of the switch. In the variable position of the range switch, a manually operated potentiometer permits continuous variation of range simulating signals from 0 to 195 miles. In the fixed position of the range switch, fixed range steps are available, from 0 to 198 miles, in 18-mile increments.

Each range selector position selects a positive bias, which is fed to the bootstrap delay circuit. In the bootstrap delay circuit, this bias and a pulse from the pulse train generator produce a delayed signal which operates a range gating circuit. In the fixed position of the range switch, the range gate produces a fixed delay gate which opens the coincidence gate to permit the passage of the appropriate pulse from the pulse train. The variable delay range pulses from the range gate, or the fixed delay range pulses from the coincidence circuit,

Figure 7-12. —Range and azimuth unit, range circuits, block diagram.

are fed to the efficiency circuit, which divides the pulse count so that only the indicated percentage of appropriately delayed reply pulses is fed to the output circuit. The output circuit converts each range reply pulse to a pulse trigger fed to the pulse generator unit.

A 15-cps and 135-cps generator provides the basic signals used by the unit for producing simulated bearing signals. The separate synchronous 15-cps and 135-cps sine waves from the generator are fed, respectively, to north reference burst and auxiliary reference burst circuits. The north burst circuit produces a pulse which serves as the north burst trigger. The auxiliary burst circuit produces eight equally spaced pulses between each pair of north burst trigger pulses.

Separate 15-cps and 135-cps sine waves from the generator are fed to phase shift resolvers. These resolvers shift the phase of the 15-cps and 135-cps sine waves, with respect to the north and auxiliary triggers, to simulate bearing information.

A 4,046-cps oscillator in the range and azimuth unit provides a 4,046-cps signal for testing range circuits in the airborne receiver-transmitter.

810
808
115

A tone pulse circuit produces 1,350-cps tone trigger pulse groups.

PULSE GENERATOR UNIT.—The pulse generator unit utilizes the tone, range, and bearing signals from the range and azimuth unit for the following purposes:

1. To produce coded pulse groups.
2. To generate random squitter pulses.
3. To combine all outputs to form a properly sequenced coded pulse train for use by the modulating circuits in the signal generator.

The tone trigger, simulated range trigger, and a squitter signal (generated within the pulse generator unit) are fed to the tone squitter circuits. A switch allows selection of separate signals or of a combined squitter-range signal, and permits the tone-range-squitter circuits to produce a properly sequenced pulse train which is fed to the burst mixing and gating circuits. The north and auxiliary trigger pulses are fed to separate reference burst circuits.

Each reference burst circuit produces properly spaced pulse groups for each trigger signal. The north reference burst consists of 12 pulses, spaced at 30-μsec intervals, and occurring at a 15-cps rate. The auxiliary reference bursts consists of 6 pulses, spaced at 24-μsec intervals, and occurring at a 135-cps rate. Since auxiliary bursts are blanked during the occurrence of north bursts, the combined reference burst signals are fed to the burst mixing and gating circuits without interfering with each other. In the mixing and gating circuits, the inputs are combined to form a properly sequenced series of pulses. These sequenced pulses are fed to the pulse coding circuit, where the spacing between pulses of a pair can be varied.

The coded, sequenced pulses are fed to the pulse generator and shaper circuits. In these circuits each pulse is used to produce a pair of 3.5-μsec pulses, spaced 12-μsec apart. All of these pulses are of equal amplitude and are fed to the modulator circuits. The variable phase 15- and 135-cps sine waves, conveying the bearing information, are fed to the modulator driver circuits and may be used to amplitude modulate the pulse pairs. The output is fed to the signal generator and is also available at a monitor jack for test purposes.

SIGNAL GENERATOR UNIT.—The signal generator unit (fig. 7-13) utilizes the output of the pulse generator to amplitude modulate any one of 126 output frequencies. This action produces an output signal which consists of RF pulses containing the range, tone, squitter, and reference bursts, all of which are amplitude modulated by the simulated bearing signals at 15 cps and 135 cps.

Any one of 42 separate crystals selected by the channel selector controls a primary crystal

Figure 7-13.—Signal generator, simplified block diagram.

811

oscillator. The signal from the primary crystal oscillator, after being multiplied and properly combined with the output of a crystal controlled 105-mc or 63-mc oscillator, provides the 126 radiofrequencies. The unit may also be used at these frequencies as a CW generator.

The composite modulating signals from the pulse generator unit enter the modulator drive circuits. After amplification, they are used to modulate various RF stages when the unit is switched to the pulse operation position. The RF signal from the output cavity is fed through a variable attenuator to an RF filter assembly. Then, via a piston attenuator, the RF signal is fed to the receiver-transmitter under test. When the receiver-transmitter under test transmits range interrogation pulses, the coupling circuit directs them to a detector which detects the interrogation pulse pairs and feeds them to the range and azimuth simulator.

The signal generator also contains circuits for measuring the transmitter output power of the receiver-transmitter under test, calibrating the level of the pulsed or CW RF output, and monitoring the various signals.

MAINTENANCE

Instructions for maintaining the TACAN beacon simulator are contained in the Service Instruction Manual, NavWeps 16-30ARM22-502, sections V and VI.

Section V, titled Organizational Maintenance is limited to service, replacement of subassemblies, and minor repair. This section contains tables for the following functions:

1. Preliminary inspection.
2. Cable interconnections.
3. Check procedures of major units.

Minor repairs in this section will be confined to the cleaning, repairing, and replacement of only those components listed in the preliminary inspection list.

Section VI, Field Maintenance, contains instructions for preventive and corrective maintenance. Preventive maintenance information covers periodic inspections of the equipment, lubrication instructions, and an overhaul schedule. Corrective maintenance information provides trouble analysis tables and a section on equipment alinement. This section also includes tables of minimum performance standards to insure that the equipment is at an acceptable performance level.

FREQUENCY METER

Frequency Meter AN/USM-26 is a precision instrument that measures frequencies to 10 megacycles automatically and displays its answers in digital form on an eight-place panel indicating system. With the use of the plug-in unit Frequency Meter Subassembly MX-1637/U (supplied as part of USM-26), the range is extended to 100 megacycles. With the use of the Frequency Converter Group AN/USA-5 (not supplied), the frequency range may be extended to 220 megacycles. In addition to making direct measurements of frequency, the set also measures period (time of one cycle of a periodic wave), time intervals, frequency ratios, and total events. It may also be used to count random events, such as those encountered in nuclear work.

PURPOSE

Because of the accuracy with which it measures frequencies, the equipment can be considered to be a new type of secondary frequency standard that replaces more elaborate installations of conventional precision frequency measuring equipment. For example, the meter has been found particularly useful for frequency measurements in quartz crystal grinding work as well as for general laboratory quality frequency measurements. Other typical frequency measuring applications for the equipment include calibration of transmitters, oscillators, signal generators, etc.

In combination with tachometer generators or other suitable transducers, the equipment can be used to make precision tachometry measurements. In tachometry work it is particularly useful for measuring the performance of high speed devices.

Time measurements that the equipment will make include pulse length, pulse interval, time delay, etc.

Since the indicating system in the equipment presents the measured frequency in up to eight significant figures, the equipment is especially useful for measuring very small frequency changes, such as are encountered when making measurements of frequency stability of oscillaators and similar frequency generators.

OPERATION

The circuit of the frequency meter can be considered to consist of seven basic sections. These are:

1. The input section, where input signals are amplified and shaped before they are fed into the counters and the control circuits. Trigger circuits in this section assure that strong, sharp triggering pulses are always supplied to the high speed circuits.

2. The time base section, which supplies the internal standard frequencies for the frequency meter. This unit consists of a 100-kc crystal oscillator and frequency multiplier and divider circuits.

3. The gate section, which opens and closes the signal path to the counter. The circuit also controls the display time and resets the counter to zero.

4. The counter section, which consists of eight cascaded scalers, each with an indicating system.

5. The frequency converter, a front panel plug-in unit which extends the basic frequency measurement range of the frequency meter from 10 mc to 100 mc.

6. The time intervals unit, also a front panel plug-in unit, which contains the adjustable threshold input channels (START INPUT and STOP INPUT) that are used for measuring the time between two electrical events.

7. The power supply, which develops all of the necessary operating potentials for the frequency meter circuits.

Time Base Section

The 100-kc internal standard frequency is controlled by a low temperature coefficient crystal, Y1. Frequency accuracy of two parts per million per week or better is obtained by maintaining the 100-kc crystal at a uniform temperature in a heater oven. The crystal oven, Z35, is wired into the primary power circuit and is on as long as the instrument is connected to the power source. A panel mounted thermometer provides a continuous indication of crystal temperature which is nominally 65°C. Oven heater circuits are shown in the power supply schematic. Figure 7-14 shows a block diagram of the complete time base.

CRYSTAL OSCILLATOR. —The 100-kc crystal oscillator (V34) in figure 7-15 is a modified Pierce circuit. Frequency can be changed ±2 cps by adjusting the capacity across the crystal. This change is made by screwdriver adjustment of capacitor C94, located at the

Figure 7-14. —Block diagram of the time base.

lower left corner on the front panel of the instrument. Larger changes can be made by adjusting capacitors C95 and C96 located on the deck behind the crystal oven.

The output from the crystal oscillator drives blocking oscillator V36A. The output voltage is also fed to the FUNCTION SELECTOR switch (S1A) for self-check operation.

EXTERNAL STANDARD FREQUENCY.—Where a primary frequency standard is available, an external 100-kc standard frequency may be connected to the 100-kc INPUT, with switch S5 in EXT position. V34 is converted to amplifier operation as shown in figure 7-15.

BLOCKING OSCILLATOR.—To reduce the loading and provide isolation from the remaining circuits, blocking oscillator V36A follows the crystal oscillator. This oscillator drives itself beyond cutoff within one cycle of operation. The action is initiated by the output signal from the 100-kc crystal oscillator (V34) and results in a sharp output pulse accurately repeated at a repetition rate of 100 kc per second. A simplified schematic of the blocking oscillator is in figure 7-16. It consists of V36A, a special iron core transformer T2, and associated components.

Gating Section

The function of the gating section is to open and close the signal path from the input amplifiers and triggering circuits to the counters by means of an electronic gate. This section also controls the display time and supplies the reset pulse to clear the previous count from the counters before the gate opens. A block diagram of the gating section is shown in figure 7-17.

BINARY GATE AND DIODE GATE.—The binary gate (V6 and V7 of fig. 7-18) is a modified Eccles-Jordan flip-flop circuit. It has the function of furnishing the signal gate with the

Figure 7-15.—Schematic of crystal oscillator.

814 618

Figure 7-16. —Schematic of blocking oscillator.

proper voltage to hold it open for a time interval between the two negative input pulses (start and stop) to the binary. The diode gate (CR5), which is controlled by the display time circuits, prevents the binary gate from being retriggered during the display time. This isolation of the binary gate is accomplished by blanking any negative triggering pulses with a high back bias placed on CR5 by the display time control tube V4. The bias is removed at the end of the display time and the system is ready to start the new count. A simplified schematic of the binary gate and diode gate is shown in figure 7-18.

To insure positive operation of the binary gate by any of the several types of driving pulses, the basic binary circuit is modified by use of R51, R52, R67, and R68. These resistors form two voltage dividing networks that apply back bias to the grid crystal CR5 or CR10 (whichever tube is cut off) and zero bias to the grid crystal of the conducting tube. Due to this bias, triggering pulses reach only the grid of the conducting tube, the back bias absorbing those that would be applied to the grid of the cutoff tube.

Each triggering of the binary gate shifts the bias so that the back bias always shields the cutoff half of the gate from any triggering pulse. The shift (due to stray capacity) takes approximately 0.7 microseconds, or somewhat longer than the 0.1 microsecond shift time of the flip-flop. This delay allows lengthy triggering pulses to die down and eliminates possible erratic triggering of the binary gate.

The source of the negative input pulse to the binary gate depends on the measurement function performed by the instrument. For period

Figure 7-17. —Gating section, block diagram.

815

Figure 7-18. —Simplified schematic of binary gate and diode gate.

measurements, the input trigger pulse is obtained from an external signal applied to the SIGNAL INPUT and goes through the amplitude discriminator (Z2) directly to the diode gate. In 10 period measurements, the external signal passes through the amplitude discriminator and the decade divider. The output pulse from the decade divider is differentiated and passes through the open diode gate (CR5) to trigger the binary gate. For time interval measurements, external signals fed to the input connectors of the time interval plug-in unit pass through the waveshaping circuits and are applied directly to the diode gate and binary gate.

During frequency measurements, the internal standard frequencies derived from the time base are fed to the amplitude discriminator and decade divider to provide start and stop signals for the binary gate.

Since the accuracy of the gate period depends upon the speed with which this circuit flips from one state to another, a flip-flop circuit similar to that found in the 10-mc high speed decade counter is used. As the circuit is triggered from one state to the other, the plate voltage of V6 is switched from +70 to +90 volts, with the plate of V7 always in the opposite state. The gate is open when the plate of V7 is at +70 volts and closed when the plate is at +90 volts. The output is taken from the plate of V7 and fed to the buffer amplifier V8A.

Counter Section

The pulse counting circuit consists of decade counters, such as those used in digital computers and nuclear instruments. Each counter performs the following two functions:

1. It divides the frequency of the incoming pulses by 10 and presents the lower frequency at its output.
2. It remembers (stores) indefinitely the number of input pulses received since it delivered the last output pulse, and displays this number by some means. Thus, when a number of counters are connected in cascade, each dividing by 10 and indicating the remainder, each digit in the total number of pulses received will be displayed.

COUNTING CIRCUITS. —The counter section of the frequency meter employs eight decade counters. Two of the decades, the 1-mc decade and the 10-mc decade, display the residual counts on meters. The six remaining decade

counters are plug-in units. Five of these (Z5 through Z9) are decade counters with a maximum counting rate of 30 kc. One counter, Z4, has a top frequency of 100 kc. The residual counts of these decades are displayed by means of neon lamps.

BASIC BINARY SCALER.—Since counters must be usable over wide frequency ranges, counting circuits must be nonperiodic. This requirement has led to the use of the Eccles-Jordan trigger circuits or flip-flops and a binary system for counting purposes.

For convenience of use, it is desirable that a counting device divide by a factor much larger than two. Therefore, several flip-flops are usually connected in cascade in a circuit such as that of figure 7-19 where four stages divide in a binary manner by a facotr of 16. That is, every 16th pulse applied to the input flip-flop results in a single output pulse from the output flip-flop, as illustrated in figure 7-20.

DECADE COUNTERS.—Because of the wide preference for decimal rather than binary dividing ratios, compounded binary systems such as that in figure 7-19 are often modified by means of a feedback circuit so as to recycle after the 10th applied triggering pulse. This operation is best described by reference to figures 7-21 and 7-22.

Starting with the output plate (pin 6, fig. 7-22) of each of the flip-flops in a low state (conducting), the plates would be as shown at position 1 in figure 7-21. If it were now possible to cut off plate current in tubes V20 and V21 (represented by waveforms B and C), their plates would go to the high state (+200 volts). This change to +200 volts would correspond to skipping from a place just after the eighth input pulse (position 1) over to a place just following the 14th input pulse (position 2) in the straight binary system (see trigger pulses opposite 4 in figure 7-21). The six plate voltage states corresponding to input pulses 8, 9, 10, 11, 12, and 13 in the straight binary system would thus be skipped. From this point, two more input pulses (trigger pulses 9 and 10 opposite 5) would return all four plates to the low (conducting) state from

Figure 7-19.—Flip-flop chain used in scale-of-16 circuit.

Figure 7-22. —Decade counter, schematic diagram.

which they started. The four stages have now completed a cycle in 10 counts instead of 16. A schematic diagram of such a feedback circuit is shown for the 1-mc decade counter in figure 7-22.

FREQUENCY CONVERTER. —The frequency converter plug-in unit extends the frequency measurement range of the frequency meter from 10 mc to 100 mc. A block diagram of the unit appears in figure 7-23.

Although the basic purpose of the frequency converter is to extend the frequency measurement range, measurement of lower frequencies can still be made. The MIXING FREQUENCY control is placed in the zero position for measurement of frequencies below 10 mc. Input signals bypass the tuned amplifier and mixer stages and are applied directly to the video amplifiers. Because of the additional gain (due to the video amplifiers), the frequency measurement sensitivity of the frequency meter up to 10 mc is increased about 20 db when the frequency converter unit is in place.

For measurement of input frequencies from 10 mc to 100 mc, signals are fed into the tuned amplifiers. These amplifiers operate in push-pull, with a tuned plate circuit consisting of two capacitors and four inductors. The plate circuit of the tuned amplifiers is tuned by setting the TUNING RANGE-MC and TUNING controls for maximum deflection of the tuning eye indicator. Adjusting the TUNING control also adjusts the 10-mc trap in the output of the frequency converter.

With the MIXING FREQUENCY control set to TUNE, the tuning eye indicator will close as

818

Figure 7-23. —Block diagram of frequency converter unit.

the unknown frequency is located. If the eye overlaps in closing, the input signal should be reduced with the GAIN control (the grid bias resistor) to protect against overloading the tuned amplifiers. If the eye does not close with maximum gain, the amplitude of the input is too small for accurate counting. The output voltages from the plates of the tuned amplifiers are applied to the grids of the balanced mixer.

The mixer tubes are dual control RF pentodes. The input signal is applied to the first control grid, while the mixing signal is applied to the second control grid. The BALANCE ADJ capacitor balances the drive from the tuned amplifiers to the balanced mixers. The BALANCE ADJ capacitors should be set to minimize the 10-mc carrier frequency at the output of the video amplifiers in the unit.

The variable cathode resistor for the balanced mixers balances the transconductance of the mixer tubes. Two capacitors neutralize the inputs to the balanced mixers.

The MIXING FREQUENCY control is now set to the frequency indicated by the dial of the TUNING control. The MIXING FREQUENCY control selects the proper frequency from the harmonic generator by switching in appropriate tuned circuits. The harmonic frequency is applied to the suppressor grids of the balanced mixer tubes where the signal is mixed with the input frequency applied to the control grids. The difference frequency, obtained at the parallel plates of the mixer tubes is fed through the video amplifiers to the counting circuits.

The total count is obtained by adding the MIXING FREQUENCY figure and the displayed count. The MIXING FREQUENCY figure is always megacycles and the displayed count is kilocycles.

The harmonic frequency generator is a sharp cutoff RF pentode. The control grid is driven by a 10-mc signal from the time base. Operating as a class C amplifier, the plate current has a high harmonic content (harmonics of the exciting voltage applied to the control grid).

TIME INTERVAL UNIT. —A block diagram of the time interval unit is shown in figure 7-24. This unit provides circuits that enable the frequency meter to measure time intervals from a minimum of 1 microsecond up to 10 million seconds with a high degree of accuracy. The time is displayed on the counters and may be read directly in seconds, milliseconds, or microseconds, as indicated in the TIME UNIT control.

Two separate circuit input channels are provided. One accepts a start signal and the other accepts a stop signal which opens and closes the electronic gate in the frequency meter. Special threshold selecting controls are provided for the trigger circuits in both the start and stop channels so that they will be actuated only by signals of predetermined amplitude, slope, and polarity. The trigger circuits shape the input waveforms into suitable start and stop trigger pulses for the binary gate. (See fig. 7-24.) TRIGGER LEVEL VOLTS switches S1 and S3 select the voltage at which the channel will trigger. These

819

Figure 7-24. —Block diagram of time interval unit.

controls are calibrated from +192 to -192 volts.

TRIGGER SLOPE SWITCHES S5 and S6 prepare the channels to trigger only from the positive or only from the negative slope of the waveform. The two controls permit each channel to be triggered by any one of the following four combinations of slope and polarity: Positive or negative slopes of positive voltages, and positive or negative slopes of negative voltages. For each of these combinations, the voltage at which triggering occurs is adjustable from approximately 1 to 192 volts. The COM-SEP switch (not shown) is provided so that the start and stop channels can be operated from the same input (COM position) if desired. The slope and level controls for each channel remain operative, permitting measurements to be started and stopped from different portions of the signal.

POWER SUPPLY. —The power supply is designed to supply all of the operating potentials required for the frequency meter. The unit provides regulated d-c voltages at +210v, +90v, +70v, and -195v, and an unregulated d-c voltage of +300v. Full wave rectifier circuits are employed with electronic regulation. The power supply also provides all of the filament power required by the vacuum tubes in the instrument.

Two separate full wave rectifier circuits are used; one supplies the positive voltages, and the other supplies -195v d. c. Electronic regulation makes the output voltage substantially independent of the load impedance. Screwdriver adjustments are provided to set all regulated voltages.

MAINTENANCE

Test equipment maintenance is covered later in this chapter. Additional details may also be found in the Service Instruction Manual for the equipment.

RADAR TEST SET AN/UPM-32

Radar Test Set AN/UPM-32 is a portable test set designed primarily for use with radar sets operating in the frequency range of

8,500 to 10,500 mc. It combines in one test set all the functions of a power meter, a frequency meter, a spectrum analyzer, a signal generator, and a general purpose synchroscope. Figure 7-25 illustrates the AN/UPM-32, indicating all of its front panel controls.

PURPOSE

The general applications of the test set are as follows:

1. Measurement of power, frequency spectrum, and frequency pulling of conventional and multipulsed radar transmitters.
2. Measurement of sensitivity and bandwidth of a radar receiver.
3. Measurement of the frequency and spectrum of a radar receiver local oscillator.
4. Adjustment of a radar receiver local oscillator.
5. Measurement of TR recovery time.
6. Observation of video signals.
7. Furnishing pulsed, FM, or CW microwave signals.

From the preceding list of applications it should be obvious that the AN/UPM-32 is a very versatile test set.

OPERATING PROCEDURES

Through the use of the master function selector switch (number 9, fig. 7-25), the internal circuits may be switched into the desired operation to perform any of the functions previously mentioned.

Power Meter Operation

When it is desired to use the test set as a power meter, input signals from a radar transmitter pass through a calibrated variable attenuator to a temperature compensated power monitor, illustrated in figure 7-26 in block form. The power monitor is composed of a bridge circuit and a power level indicating meter calibrated in milliwatts and dbm (decibels relative to one milliwatt).

Frequency Meter Operation

When the frequency meter function of the test set is used, an absorption type frequency meter is tuned to resonance. (See fig. 7-26.) The resonant frequency meter cavity causes a reduction of the power level in the microwave section at the frequency to which the cavity is tuned. This reduction of power, at the resonant frequency, appears as a dip on the power monitor meter or on the screen of the synchroscope. The resonant frequency (in megacycles) is indicated directly on a front panel counter (22, fig. 7-25) which is geared mechanically to the tuning mechanism of the cavity. The power meter and frequency meter portions of the AN/UPM-32 closely resembles the TS-147 frequency-meter test set in construction and operation. Therefore, with an understanding of this portion of the AN/UPM-32 the technician should have little trouble in the operation and use of the TS-147 if the AN/UPM-32 is not available.

Spectrum Analyzer Operation

For the spectrum analyzer function, the test set's klystron oscillator is frequency modulated by the sawtooth output of a sweep generator. (See fig. 7-27.)

The radar transmitter signal to be observed and the klystron oscillator signal are combined in a mixer to produce heterodyne frequencies which are fed to an IF amplifier. For each radar transmitter pulse, a frequency component of the pulse beats with the klystron oscillator signal to produce a 45-mc IF signal. For successive radar transmitter pulses, a different frequency component causes the 45-mc beat frequency to appear because the klystron oscillator is frequency modulated. The detected IF signals are amplified and applied to a cathode-ray tube. Since the horizontal deflection system of the cathode-ray tube is driven by the same sawtooth used for klystron modulation, the CRT pattern is a plot of frequency versus relative power for the input signal.

The test set also includes a gating circuit which permits the observation of the spectrum of any pulse in the output of a multipulsed radar transmitter. For this operation, the radar synchronizer is used to feed a pretrigger to the test set gating circuit to avoid triggering on the wrong RF pulse. This circuit, in turn, generates a pulse which gates the IF amplifier so that any signals applied during the gating period pass through the amplifier. The gating period is long enough to permit only the frequency samples from one radar transmitter pulse to pass through the IF amplifier. The gating pulse may be delayed relative to the pretrigger for the desired pulse selection.

Figure 7-25. —Radar Test Set AN/UPM-32, front panel controls.

This portion of the AN/UPM-32 closely resembles the operation of the Sepctrum Analyzer TS-148 with the exception of the gating circuit function used for testing multipulsed radar transmitters. This feature is not available with the TS-148. However, with an understanding of the AN/UPM-32 spectrum analyzer operation, the AT should have little trouble understanding and operating the TS-148 for spectrum analyzation if the AN/UPM-32 is not available.

Signal Generator Operation

When the test set is used as a signal generator, it supplies FM, pulse modulated, externally modulated, or CW microwave signals. This portion of the AN/UPM-32 is illustrated in block form in figure 7-28.

For the FM and pulse modulated signals, internal circuits provide the modulating waveforms, but a trigger must be provided by an

external source. Any desired type of modulation waveform can be applied to the klystron osicllator, and the test set will provide correspondingly modulated RF signals. The power level and frequency of all output signals are adjustable to the desired level within the limits of the test set.

Synchroscope Operation

When the test set is operated as a general purpose synchroscope, a video signal is applied to the video amplifiers. The amplified signal is applied to the vertical deflection circuit of the cathode-ray tube as illustrated in block form in figure 7-29.

This video signal can be externally applied, or it may be an internal signal taken from the mixer crystal (detector). The sweep generator, which drives the horizontal deflection system of the cathode-ray tube, must be triggered and synchronized with the video signal, either by an external trigger source associated with the video signal or by the detected RF pulse from the radar transmitter.

Microwave Assembly

The microwave assembly makes possible the measurement of the power level and frequency of input and output signals. The assembly consists basically of a block containing waveguides and attenuating sections. Within the assembly both the klystron signal and RF input signals are mixed to obtain a spectrum pattern. Signal flow in the assembly depends upon the setting of the function selector switch to the desired mode of operation.

With the function selector switch on MIXER position, energy flow in the assembly is illustrated in figure 7-30. The power set attenuator adjusts the power level of the klystron signal. Because the klystron oscillator is sawtooth modulated by the sweep generator circuits (fig. 7-27), its output frequency varies linearly during the sawtooth excursion. Therefore, if the frequency meter is tuned to a frequency within the range covered by the klystron output, a sharp reduction in power level occurs at this

Figure 7-27. —Spectrum analyzer operation, simplified block diagram.

Figure 7-28. —Signal generator operation, simplified block diagram.

particular frequency. This reduction appears as a dip in the pattern displayed on the CRT indicator. The frequency of the klystron may then be read directly, in megacycles, from the frequency meter Z304.

With the function selector switch in the NORMAL or GATED position, two signals are present in the microwave assembly. (See fig. 7-31.) The klystron signal and the transmitter signal are mixed in the mixer crystal which produces heterodyne frequencies. The 45-mc component appearing during each radar output pulse passes through a tuned filter network to the IF amplifier stages. Because of the linear sawtooth modulation applied to the klystron, the klystron signal beats with a different frequency component of the radar output during each transmitted pulse interval to produce this 45-mc beat frequency. Hence, the amplitude of each 45-mc pulse is a measure of the power contained in the particular magnetron frequency component producing it. The magnetron spectrum is thus produced and appears on the CRT indicator. The importance of this presentation lies in the fact that with it a radar transmitter can be tuned to give a spectrum in which the greatest possible portion of the high power frequency components falls within the pass band of the radar receiver.

Figure 7-29. —Synchroscope operation, simplified block diagram.

When the function selector switch is placed in the PWR-FREQ METER position, the radar transmitter power is fed through the microwave assembly as shown in figure 7-32. The RF switch is closed; hence there is no power division at the tee junction nor can any klystron power reach the thermistor mount. This permits measurement of the power level of the incoming signal. The step attenuator should be at its minimum (LO) position.

For the PULSE MOD, FREQ MOD, and EXT MOD positions of the function selector switch, signal flow is shown in figure 7-33. The power level of the klystron RF signal is set by the power set attenuator. The frequency of the signal is indicated by the frequency meter which is used in conjunction with either the power level indicating meter or the synchroscope pattern on the CRT. Since there is an equal division of power in the tee junction following the RF switch, the reading of the power level bridge meter, as modified by the DBM attenuator dial reading, gives an accurate indication of the power level of the test set output signal. The signal reaching the mixer crystal is detected, and the signal, which is the modulation waveform, can be viewed on the CRT by setting the signal switch at INT if desired.

Trigger Detector Assembly

The trigger detector assembly (Z303, fig. 7-33) consists of a removable mount attached to the rectangular waveguide section at the input of the microwave assembly. The mount contains a crystal rectifier element (CR302) and functions as a fixed tuned detecting section. Isolation from the main waveguide is provided by an iris which attenuates the energy from the main waveguide about 35 db to protect the crystal from burnout.

DBM Attenuator

The DBM attenuator consists of a rectangular glass vane coated with a resistive material. The vane is mounted inside the waveguide parallel to the narrow wall, and its position is continuously adjustable (by the DBM control) from

Figure 7-30.—Energy flow in microwave assembly, function selector switch at MIXER.

the narrow wall toward the center of the waveguide. The maximum attenuation introduced by the vane (near the center) is approximately 50 db. The calibration of the DBM dial accounts for this attenuation and the known losses in the microwave block.

Step Attenuator

The step attenuator is constructed in the same manner as the DBM attenuator. The step attenuator is controlled by the ATTENUATION switch, which has two settings, HI and LO. In the HI position, the vane is near the waveguide center; in the LO position, it is adjacent to the narrow wall. For the HI position of the switch, the step attenuator introduces about 50 db of attenuation in the waveguide run.

RF Switch

The RF switch consists of a cylindrical element which closes off the waveguide leading to the klystron when the function selector switch is on the PWR-FREQ METER position. The axis of the switching device is paralled to the broad walls of the waveguide. The device has a rectangular hole through it, which lines up with the waveguide for the open position and rotates through a quarter turn to close off the waveguide run to the klystron. A metallic window which projects part way across the guide opening inside the device serves as an impedance matching device for the waveguide tee.

RF Oscillator

The microwave oscillator tube (V301) used in the test set is a reflex klystron which operates on the principle of velocity modulation. The klystron may be tuned either mechanically or electrically. Mechanical tuning is accomplished from the top of the klystron by the OSC FREQUENCY control. Electrical tuning is accomplished by the modulation sawtooth from the modulation sweep generator circuits and by the REFLECTOR control.

Figure 7-31. —Energy flow in microwave assembly, function selector switch at NORMAL or GATED.

NOTE: A detailed discussion on the operation of the reflex klystron is given in chapter 12 of this course.

Power Set Attenuator

The power set attenuator consists of a small rectangular glass vane coated with a resistive material. The adjustment of the vane position within the waveguide is continuous, but the assembly is not calibrated. For the maximum attenuation position near the waveguide center, the attenuator decreases the level of the klystron output signal by 20 to 25 db.

Frequency Meter

The frequency meter (Z304) consists of a circular high-Q cavity with a movable concentric tuning plunger. The frequency meter is fitted into the microwave assembly and coupled to the waveguide by means of a circular iris, and the entire assembly is hermetically sealed. The tuning plunger mechanism is geared to the frequency counter which indicates the resonant frequency of the cavity in megacycles.

Thermistor Mount Assembly

The thermistor mount assembly (Z306) is comprised of a short waveguide section terminated in a housing which contains a thermistor bead. The bead is sensitive to microwave energy, and its resistance changes in proportion to the level of energy in the waveguide. The assembly is mounted to the microwave section and fixed tuned at the factory. A cylindrical subassembly is located on one side of the thermistor mount assembly to hold a disk thermistor. This thermistor has a negative temperature coefficient of resistance. The resistance changes in the disk thermistor compensate the power level bridge circuit for the effects that changes in the ambient temperature produce in the resistance of the thermistor bead.

Figure 7-32.—Energy flow in microwave assembly, function selector switch at PWR-FREQ METER.

Mixer Assembly

The mixer assembly (Z305) is similar in construction to the trigger detector assembly (Z303), and it contains the same type crystal cartridge. When the function selector switch is on the MIXER, PWR-FREQ METER, GATE ADJ, PULSE MOD, EXT MOD, or FREQ MOD position, the mixer crystal acts as a simple RF detector. For operation in the NORMAL and GATED positions of the function selector switch, the radar transmitter signal and the klystron signal are both present, and the output of the mixer contains beat frequencies because of the nonlinear detection characteristic of the crystal. The mixer assembly also contains a 3-db isolation pad which is adjusted when installed and must not be disturbed by the field maintenance technician.

MAINTENANCE

The information presented in this section is intended to aid the Aviation Electronics Technician in the prevention and correction of troubles in the Radar Test Set AN/UPM-32.

The technician should bear in mind that the operation of this equipment involves high voltages which are dangerous to life. Maintenance personnel must observe safety regulations at all times.

No maintenance should be attempted on the equipment without the test set's Service Instruction Manual for ready reference. Section V of this manual lists in table form the minimum performance standards of the test set. It includes the purpose of the check, procedure, normal indications, and a list of possible causes of abnormal indications. Section V of the Service Instruction Manual also lists a step by step procedure for isolation of a trouble to a faulty circuit, group of circuits, or part. A system of symbols is used in the check charts for indicating in the equipment where test connections are made for measuring or observing electrical data. The symbols are divided into three classes: major, secondary, and minor

Figure 7-33.—Energy flow in microwave assembly, function selector switch at PULSE MOD, FREQ MOD, or EXT MOD.

test points. The major test points are assigned to critical points in circuits interconnecting assemblies or at input/output connections. These points are used to localize a trouble to a particular assembly or group. Secondary test points are generally assigned to critical points between circuits within an assembly. These points are used in localizing trouble to a particular circuit of the assembly. Minor test points are assigned to points within circuits bracketed by secondary test points. These are used to isolate the trouble to a particular stage of the circuit.

Section V of the Service Instruction Manual also lists in detail the removal and replacement instructions for assemblies, subassemblies, and parts which might be found faulty in the performance and trouble analysis checks. It lists the step-by-step procedure for minor repairs and adjustments necessary after the replacement of parts for the test set to meet the minimum performance standards.

Calibration

The complete procedures for alinement and adjustment of the test set are contained in section VI of the Service Instruction Manual. The control or adjustment described in the manual need only be checked occasionally or whenever a tube or detail part is replaced in the circuitry directly associated with any given control.

Section VI lists the detailed procedures for alining the following:

1. IF amplifier assembly.
2. Video amplifiers.
3. Pulse generator assembly.

It also lists in table form a complete schedule for maintenance inspections, listing the item to be checked, inspection required, and the time interval between inspections. (NOTE: The test set should be turned in to the activity's overhaul center after each 2,000 hours of operating time.)

Another important maintenance aid included in section VI is the description of bench test setups utilizing the test set. It includes cabling details for interconnecting the test set and the test equipment used in the minimum performance procedures discussed previously.

Section VII of the Service Instruction Manual consists of information and diagrams used in both maintenance and alinement. The diagrams will be especially useful in conjunction with the trouble analysis charts. All the test points noted in the trouble analysis charts are indicated on the schematic diagrams in this section. It also contains a complete set of waveform diagrams (photographs) which appear at the various designated test points.

TEST SET AN/UPM-44C

Radar Test Set AN/UPM-44C is supplied as associated equipment to Radar Set AN/APS-82. A complete description of the radar test set is covered in the Service Instruction Manual, NavAer 16-30UPM-44-502.

The radar test set consists of the test set assembly transit case, and accessories. The front panel of the test set assembly is shown in figure 7-34.

The test equipment is designed for use with S-band radar systems and may be used for the following purposes:

1. Measure receiver bandwidth sensitivity, recovery time, and local oscillator frequency.
2. Measure transmitter power and frequency.
3. Tune local oscillator.
4. Test and tune duplexers, AFC systems and rotating joints.
5. Provide visual indication of the magnetron and local oscillator spectra.
6. Observe magnetron pulling.
7. Visual indication of video signals.

With the expection of frequency coverage, the UPM-44C is similar to the UPM-32. Therefore, further detailed coverage is not presented here.

PULSE GENERATOR

The equipment discussed in this section is a combination pulse generator and synchroscope. It is capable of furnishing, displaying and measuring pulse test signals.

PURPOSE

The pulse generator SG-30/UP has been designed to furnish rectangular voltage pulses of adjustable duration, amplitude, and repetition frequency. These pulses follow trigger pulses by an adjustable time interval. The equipment may be triggered by an external signal, or by an internally generated audio signal. Internally generated pulse, trigger, and audio signals are made available at output terminals on the front panel. With the synchroscope provided in the same unit, the equipment is capable of accurately determining the waveshape, amplitude, duration, and time relationship of the output pulses. This equipment is suitable for use in maintaining airborne or ground electronic equipment. The design and construction of the unit makes it adaptable for work performed in laboratories or maintenance shops located on land or aboard ships.

OPERATION

Pulse Generator SG-30/UP is basically a pulse generator and a quantitative cathode-ray synchroscope combined into one compact unit. It produces rectangular voltage pulses of adjustable width, duration, amplitude, repetition rate, and polarity, and provides means by which these characteristics may be observed and accurately measured. A simplified block diagram (fig. 7-35) shows the interrelationship of the various circuits employed.

The rectangular voltage pulses, generated by the pulse generator, are available at the PULSE OUTPUT terminal for coupling to the equipment under test. Polarity is selected by manipulation of the PULSE POLARITY switch.

Triggering of the pulses may be accomplished either by means of the output of the RC oscillator or by external signals coupled to the SYNC INPUT terminals. These excitation (triggering) signals are coupled to the trigger generator which converts them into sharp trigger pulses. The output of the trigger generator is coupled to both the pulse generator and the sweep generator through separate variable delay circuits, allowing the pulse and sweep circuits to be started independently of each other. The triggers are also made available at the TRIGGER OUTPUT terminals for use in external circuits.

830

Figure 7-34.—Radar Test Set AN/UPM-44C.

Since both the pulse generator and the sweep generator receive the same triggering signal, synchronization of pulses and sweep is automatic for internally generated pulses. For externally generated pulses it is necessary to adjust the TRIGGER RATE and TRIGGER RATE MULTIPLY by controls to obtain the proper trigger rate for synchronization.

The output of the RC oscillator is a sine wave whose frequency may be varied between 20 and 20,000 cycles per second. Since this is used for excitation of triggering signals, it provides for variation of the pulse repetition rate between 20 and 20,000 pulses per second. In addition to providing excitation for the trigger generator, the output of the RC oscillator is also made available at the AUDIO OUTPUT terminals for external applications.

Signals which are to be observed and measured are coupled to the vertical amplifier by means of the VERTICAL INPUT SELECTOR switch. The signal may be any of the following:

1. The positive or negative pulse from the pulse generator.

2. An external signal coupled to the VERTICAL INPUT terminals.

Figure 7-35.—Pulse generator, overall block diagram.

3. The output signal from the vertical calibrator for making voltage amplitude measurements.

The vertical calibrator provides two horizontal traces on the cathode-ray tube screen with vertical spacing which indicates the peak to peak voltage at the vertical input connection. The front panel allows selection of voltages at 0.5, 5, and 50 volts with an accuracy of ± 5 percent.

The marker generator produces pulses of accurately determined frequencies which are mixed into the vertical amplifier. These pulses are presented on the cathode-ray tube screen as pip type markers to provide for time calibration of the trace.

The standby heater, energized when the POWER switch is in the OFF position, raises the average temperature of the set to a minimum of 6° C above the ambient temperature with the equipment out of its transit case. This provides protection from harmful effects under high humidity or extremely low temperature conditions.

The fan operates continuously when the POWER switch is in the ON position. It provides forced air cooling during operation of the set.

MAINTENANCE

Refer to the section on test equipment maintenance later in this chapter, for a discussion of typical maintenance procedures applicable to the pulse generator. Additional details may also be found in the Service Instruction Manual for the equipment.

INSULATION TEST SET

The ohmmeter ZM-14A/PSM-2 is designed to measure insulation resistance from 0 to 1,000 megohms utilizing a testing voltage of 500 volts d.c. The unit consists principally

of a hand cranked a-c generator; a terminal board assembly containing a rectifier, resistors, a capacitor, and neon glow lamps; and a meter. These major component parts are housed in a die cast aluminum alloy dust and moisture resistant case provided with a removable bottom plate. On the outside of the case are a crank, two indicator buttons, two binding posts, a semicircular opening through which the meter is read, and a meter adjustment screw cover. Turning the crank in either direction until the indicator buttons glow steadily red, generates 500 volts d.c. testing voltage which is available at the binding posts. When testing insulation, the meter pointer will indicate the resistance in megohms.

OPERATING PROCEDURES

Before attempting to connect the insulation test set, be sure that the line, apparatus, or circuit to be tested is disconnected from its power supply in accordance with safety instructions. Ground the line, apparatus, or circuit to be tested to discharge any capacitors connected to it.

To measure resistance, perform the following steps:

1. Connect the side spade type terminal lug (black) of the test lead to the GND binding post on the ohmmeter.
2. Attach the alligator clip (black) of the test lead to the insulation or side of the circuit nearest ground potential.
3. Connect the other side spade type terminal lug (red) of the test lead to the L binding post on the ohmmeter.
4. Attach the other alligator clip (red) of the test lead to the conductor to be tested.
5. Turn the crank in either direction at the minimum speed required to provide steady illumination of the indicator buttons. (See fig. 7-36.)

NOTE: Do not turn the crank faster than necessary to keep buttons illuminated as the output from the voltage regulator will be greater than required.

6. Read the resistance (in megohms) offered by the material being tested on the indicating meter. If the resistance is more than 1,000 megohms the meter pointer will stay at rest over the infinity mark(∞) indicating that the resistance of the insulation being tested is beyond the range of the meter.

THEORY OF OPERATION

The activating force for the ohmmeter is supplied by manually turning the crank. The crank is connected through the gear train to the rotor of the a-c generator G101. (See fig. 7-37.)

The generated a-c voltage is converted to a d-c voltage by the rectifier CR101. The d-c output of the rectifier is filtered through capacitor C101 to minimize the line ripple which exists as a result of converting a-c voltage

Figure 7-36.—Ohmmeter ZM-14A/PSM-2.

Figure 7-37. —Schematic wiring diagram of ZM-14A/PSM-2.

to d-c voltage. Resistor R103 operates in conjunction with the neon lamps to regulate the d-c output voltage of the rectifier as required to assure maximum performance from the neon lamps. Eight neon lamps, E102 through E109 inclusive, connected in series, are illuminated by the d-c voltage from the rectifier and serve to control the output voltage at approximately 500 volts d. c. The light from the neon lamps is transmitted through two clear lucite rods and is visible on the front of the equipment. This provides visual indication that the hand crank is being turned at the proper speed to supply the required test voltage. Excessive crank speed produces only a slight rise over 500 volts. As the crank is rotated, a 500-volt potential is applied across a series circuit consisting of R104 and M101 in parallel with R106 and the unknown resistance. The current flowing in this series circuit, as indicated by the meter M101, is determined by the value of the unknown resistance. Since all other factors in the series circuit are constant, the current through the meter indicates the true value of the unknown resistance directly in megohms as determined by the relationship known as Ohm's law.

One adjustment and a guard circuit for the indicating meter are provided to insure correct readings. The external infinity adjustment screw provides a mechanical means of setting the pointer in relation to the infinity mark. Resistor R105 is connected between the case and the line (L) side of the circuit and acts as a protective or guard circuit. In the event of leakage due to high humidity, salty atmosphere, or the like, the leakage would pass back into the circuit in advance of the meter, thereby preventing an error, due to the leakage, in meter reading.

MAINTENANCE

The operator should check the initial adjustments of the ohmmeter. This consists of checking the voltage output of the a-c generator G101 and adjusting if necessary. Also check the zero and infinity positions of the meter pointer and adjust if necessary.

Preventive Maintenance

To insure continuity of service at peak performance, the following maintenance procedures and electrical checks should be performed:

1. Monthly. Perform the initial adjustments of the ohmmeter. These are the zero and infinity adjustments.

834

2. Semiannually. Check the voltage output of the ohmmeter by connecting an electronic voltmeter (0 to 1,000-volt d-c range) across the output terminals L and GND. Turn the crank at the operating speed. The output voltage should be 480 to 520 volts d.c.

3. Annually. Remove the generator G101 and oil the permanent magnet rotor shaft bearings with lubricating oil. To prepare for oiling, operate the generator at operating speed for approximately 5 minutes to warm the bearings. Then, holding the generator with the bearing on the crank side uppermost, apply three drops of oil to the bearing adjacent to the shaft, using a toothpick or similar means to control its placement. Continue, a few drops at a time, until the bearing is saturated.

Apply the same amount of oil to the bearing on the gear train side of the generator. Apply oil between the pinion and the thrust washer. Wipe up any surplus oil. No lubricant is to be applied to the gears.

Corrective Maintenance

To locate troubles, repair, or adjust the ohmmeter the methods outlined later in this chapter under Test Equipment Maintenance should be used. A troubleshooting guide is given in the Service Instruction Manual for finding the trouble. After locating the trouble, use the appropriate section of the manual for its correction.

The calibration procedure for this equipment is the same as that in the initial adjustment section mentioned under preventive maintenance.

The ZM-14A/PSM-2 is being replaced by the ZM-14B/PSM-2. This unit has a black bakelite case and its external appearance is somewhat different from that of the ZM-14A/PSM-2. However, the operating range and basic functions of these two units are identical.

RF SIGNAL GENERATOR

Signal Generator AN/USM-44A is the nomenclature assigned to the TS-510A/U signal generator and its assessories. This equipment is complete, self-contained, and transportable. It includes, in addition to the signal generator itself, the following accessories: A watertight transit case, power and RF cables, connector adapters, and an output fuse holder for protection of the RF output attenuator.

PURPOSE

The AN/USM-44A is a general purpose test equipment capable of furnishing accurately adjustable radio frequency signals from 10 to 420 megacycles. The instrument may be amplutude modulated by internally generated sine waves, or by externally applied sine waves or pulses. The set includes a built-in cyrstal controlled heterodyne calibrator which permits the operator to adjust the output frequency to a high degree of accuracy. The instrument features direct reading meters and controls throughout.

OPERATING PROCEDURES

The Operating Instruction Manual for the AN/USM-44A outlines step by step procedures for operating the equipment in each of the following modes of operation:

1. Continuous wave.
2. Internal sine wave modulation.
3. External sine wave modulation.
4. External pulse modulation.

The manual also furnishes the operator with instructions for using the frequency calibrator and contains a section on signal generator loading considerations.

THEORY OF OPERATION

The signal generating circuits are shown in block diagram form in figure 7-38. The unit contains a regulated power supply which is not shown in the block diagram.

The RF oscillator generates a variable frequency RF signal which is fed through a buffer and power amplifier to the output circuit. The oscillator is of the Colpitts type, and is carefully designed for high stability.

The buffer isolates the oscillator from the power amplifier and minimizes interaction between the two circuits.

The RF power amplifiers receives both the RF and the modulation signals and amplifies the RF energy for application to the output attenuator. The RF amplifier receives variable bias from the modulator which permits adjustment of the power level fed to the output attenuator.

The power monitor samples the RF energy fed to the output attenuator and indicates the power and voltage level on a front panel meter. The output attenuator obtains the monitored

Figure 7-38. —Signal circuit block diagram.

RF energy from the power amplifier, applies the selected degree of attenuation, and conducts the energy to the front panel output jack.

The beat frequency calibrator generates harmonics of the 5-mc signal obtained from the crystal, as well as harmonics of the 1-mc signal obtained from a tuned circuit and mixes these harmonics with the RF output signal coupled from the RF amplifier. The resultant beat frequency signal is amplified and fed to the front panel headphone jack.

The internal modulation oscillator generates either a 400- or 1,000-cps sine wave for application to the modulator. The modulator receives all modulation signals for application to the RF power amplifier and also supplies variable bias to the amplifier for control of the RF output power level.

The modulation measuring circuits receive detected modulation from the RF power monitor, amplify and rectify it, and indicate the modulation percentage directly on a front panel meter.

RF Oscillator

The RF oscillator generates a sine wave signal from 10 to 420 mc in 5 frequency bands. The Colpitts oscillator circuit is tuned by a precision split stator capacitor and 5 separate RF transformers. The tuned circuit components are specially constructed for high stability.

RF Buffer

A loosely coupled secondary winding on each of the RF oscillator coils couples RF energy from the oscillator to the buffer stage. The buffer stage is connected as an untuned grounded grid amplifier and serves to isolate the oscillator circuit from the effects of the modulation signal at the cathode of the power amplifier circuit. The use of the buffer reduces incidental frequency modulation to an extremely small value.

RF Power Amplifier

The RF power amplifier amplifies the energy received from the buffer for application to the RF output attenuator. The circuit is connected as a grounded grid, cathode modulated amplifier. The plate circuit is tuned in the same manner as the oscillator, with a similar split stator capacitor and five coils. The amplifier

836

capacitor is provided with a mechanical linkage, controlled from the front panel, that allows the rotor plates to be shifted from their normal tracking position. This control allows the amplifier tuning to be separately adjusted for maximum output at all frequencies.

Output Attenuator and RF Power Monitor

A piston attenuator is used to control the power obtained from the RF power amplifier. The housing for the attenuator projects through the rear of the RF generator housing and terminates, open ended, close to the RF amplifier plate circuit inductor. The nonresonant, single turn pickup loop at the end of the attenuator probe couples energy to an impedance matching network, then through a section of double shielded coaxial cable to the RF OUTPUT jack. The probe has a movable sleeve in the probe body which allows minor adjustments of the internal impedance of the generator so that a minimum standing wave ratio is obtained when the output jack is terminated in a 50-ohm resistive load.

The RF power level which is fed to the attenuator is sampled and continuously monitored. This power level is indicated in both volts and decibels over a limited range, on the front panel power level meter. A calibration mark on the meter establishes a predetermined amount of power fed into the attenuator for direct reading of the output attenuator dial calibrations.

Frequency Calibrator

The frequency calibrator consists of a crystal controlled oscillator, a mixer, and a 75-db resistance coupled amplifier. The accuracy of the crystal oscillator allows the frequency dial calibration to be set very accurately at the checkpoints. The calibrator is turned on as long as the signal generator is turned on.

Modulator Section

The purpose of the modulator section is threefold: To generate 400-cps and 1,000-cps sine waves for internal modulation of the generator; to amplify all modulation signals for application to the RF power amplifier; and to control the power level obtained from the RF amplifier for all types of operation by varying the bias on the RF amplifier. The modulator consists of a Wein bridge type oscillator, a limiter, amplifiers, a cathode follower output stage, and an output level control tube.

Modulation Measuring Circuits

The modulation measuring circuits indicate the degree of sine wave modulation of the RF output signal directly in percentage between 0 and 100 to an accuracy of 10 percent or better. These circuits consist of a stabilized wideband amplifier and a bridge type meter circuit. The circuit amplifies the detected modulation from the RF power monitor circuit, rectifies it, and applies the resultant d-c voltage to the meter bridge. Being a peak reading instrument, the meter indicates the modulation percentage of most waveforms that are applied to the EXT MOD jack. The meter is calibrated to indicate the percent modulation of a given amount of RF carrier power.

Power Supply

The power supply for the signal generator consists of two electronically regulated high voltage supplies, one providing -165v d.c., the other providing +225v d.c. Each regulator is supplied from a full wave bridge type selenium rectifier. The power transformer supplies a-c heater voltage for all tubes except the RF oscillator and power amplifier. These tubes receive constant heater voltage from a separate circuit.

MAINTENANCE

The Service Instruction Manual for the AN/USM-44A contains detailed maintenance information. Sections V and VI of this manual are devoted to maintenance at different levels.

Preventive Maintenance

The AN/USM-44A signal generator requires no special preventive maintenance other than a general alertness for the effects of misuse, loose controls, condition of cables and connectors, and possible damage that may be evident in the general appearance. The attenuator and frequency drive mechanisms should be inspected every 6 months for dryness of lubrication. Avoid overlubrication. If the signal generator

837

has been subjected to unusual conditions, excessive moisture, dust, heat, vibration, etc., the instrument should be removed from the cabinet and inspected for dirt or moisture accumulation, loosened components, or any possible sign of damage. Refer to the Service Instruction Manual for specific lubrication points and recommended lubricants when servicing the equipment.

Corrective Maintenance

As previously mentioned, the Service Instruction Manual contains two sections on maintenance. Section V is the organizational maintenance section and contains information and maintenance charts for use by squadron personnel. The only adjustments listed for accomplishment at this level are the power supply voltage adjustments and the modulation meter zero set.

The instructions in Section VI are an extension of those listed in Section V. These instructions include tube replacement, component replacement, calibration procedures and complicated tests which require greater skill and more precise instruments than those described in Section V. Replacement procedures are grouped at the beginning of the section followed by recalibration and test procedures for the individual sections of the equipment.

SYNCHRO ALIGNMENT SET

Synchro Alignment Set TS-714/U (fig. 7-39) is a portable, general purpose test set used to check the alinement of synchros or resolvers. It can be used to aline any 400-cps synchro or resolver. In addition to its high sensitivity, the test set has an additional advantage in that it can also supply excitation voltage for the synchro or resolver being alined.

The test set basically consists of a bandpass amplifier and power supply, a synchro or resolver excitation supply with outputs from 3 to 115 volts rms, and switching circuits. The output voltages from the synchros or resolvers are applied to the amplifier, the output of which is fed to a phase sensitive detector circuit. The detector's output is metered by the microammeter. A meter switch selects the meter sensitivity from 300 volts full scale to 0.1 volts full scale, plus a calibrate and off position.

1. Excitation switch. 2. Microampere meter. 3. Meter switch. 4. Function switch.

Figure 7-39. —Synchro Alignment Set TS-714/U, front panel.

The meter has a zero center scale and indicates zero when the synchro or resolver is adjusted to either of its two nulls. The synchro or resolver is adjusted to a null position with the function switch in the ZERO position. When the null is reached, the function switch is switched to the POL position and note is taken of the meter reading. Then the function switch is returned to ZERO position and the synchro is rotated 180° to its opposite null. When the opposite null is reached, the function switch is again switched to the POL position and a note made of the reading. The correct null will be the one indicating the lowest reading with the function switch in the POL position. When the synchro is adjusted to this null, it is electrically zeroed with the correct polarity.

For more detailed instructions on the use of the TS-714/U, consult the Operation and Service Instruction Manual.

Maintenance procedures for the test set follow the general outline presented in the following section under the heading Test Equipment Maintenance.

TEST EQUIPMENT MAINTENANCE

Some of the test equipments discussed in this chapter require special maintenance techniques. These have been mentioned as a part of the detailed coverage for the specific equipments to which they apply. In the following paragraphs a more general discussion of test equipment maintenance, applicable to most test equipment is, discussed.

TYPES OF MAINTENANCE

Maintenance personnel must be prepared to repair and adjust certain types of test equipment should it fail in operation. The trouble must be located, and after repairs or replacements have been made, the equipment must be tested and adjusted to conform to the original system specifications. Maintenance personnel must endeavor to find the source of the trouble that causes equipment failure, particularly when the trouble is a recurrent one. The recurrence of a fault usually indicates that the effect, not the cause, has been remedied.

As with the other kinds of electronic equipment, the two basic types of maintenance for test equipment are preventive maintenance and corrective maintenance.

Preventive Maintenance

Preventive maintenance, as performed on the organizational maintenance level, is of major importance. Preventive maintenance is a systematic series of operations that can be performed on all electronic equipment at regular intervals. The purpose of this maintenance is to eliminate, whenever possible, major breakdowns and unwarranted interruptions in service. Through careful and conscientious efforts it is possible to keep this equipment operating at top efficiency at all times. By preventing breakdowns, valuable time can be saved at the field and depot levels of maintenance. The importance of this type of maintenance cannot be overemphasized. Electronic test equipment can only be utilized when the equipment is functioning normally and at maximum efficiency. It is vitally important that electronic maintenance men maintain this equipment properly.

These instructions have been compiled to serve as a guide for a properly organized approach to preventive maintenance. It is suggested that the general techniques outlined in the following paragraphs be utilized whenever possible.

FEEL.—The feel operation is utilized to check rotating machinery and parts that either radiate heat or normally vibrate. This is a check for overheating as well as for parts that are not working.

NOTE: It is important that the feel operation be performed as soon as possible after equipment shutdown. This operation is always performed before attempting any other maintenance work.

INSPECTION.—This is the most important operation in the preventive maintenance program. An untrained observer will have a tendency to overlook minor troubles. It is entirely possible that these troubles may not cause equipment failure at the time when they are first noticed, but after long hours of operation may be the cause of major breakdowns. The service technician should make every effort to become familiar with the complete operating system and the indications of normal functioning of the equipment.

Inspection of the equipment should consist of carefully observing all parts associated with the equipment, noticing their color, placement,

839

state of cleanliness, etc. When performing this operation, look carefully for the following conditions:

1. Overheating. This is indicated by discoloration, blistering, or bulging of the parts. Leakage of chemical compounds from containers such as electrolytic capacitors gives warning of future breakdown.

2. Placement. Careful observation as to the position of all leads and cables should be made. The original position of all parts and interconnecting leads is shown pictorially in the manual for the equipment.

3. Cleanliness. Careful examination of all corners and recesses in the equipment for the accumulation of dust should be made. All parts, electrical connectors, and soldered joints should be free of foreign matter.

4. Tightness. All connections, mechanical or electrical, should be checked carefully for tightness.

CLEAN, ADJUST AND TIGHTEN. —These operations are considered to be self-explanatory. Familiarity with the equipment and the service manual will facilitate these operations.

VACUUM TUBES. —The technician should inspect all glass and metal tube envelopes for accumulation of dust and signs of corrosion. When such signs exist, a potential danger point also exists.

Inspection of the tubes' physical seating within their sockets should be made. This inspection is made by pressing the tubes into their respective sockets. Do not perform this check by withdrawing or rotating the tube forcibly within its socket. Such movements tend to weaken both mechanical and electrical connections associated with the tubes.

All connections to tube sockets should be clean and tight. If the connections show signs of dirt or corrosion, clear them; also tighten them when necessary. Whenever stranded wire is used for electrical connections, observe carefully, using a small mirror when necessary, the placement of each strand of wire. It is possible for single strands to become misplaced, causing external shorts across tube elements.

Periodic cleaning of all vacuum tubes is essential. Do not permit dust or dirt to accumulate on either the tubes or their respective sockets. Remove all dust and dirt from the glass or metal envelopes with a clean, lint-free cloth. When absolutely necessary, it is permissible to remove corrosion, oxidation, or foreign matter from the tube sockets using very fine sandpaper. Never use emery paper.

Examine all tube clamps, caps, and supporting parts to assure a tight fit. These parts are made of heavy gage metal which can withstand the application of pressure.

CAPACITORS. —Inspection of the terminals of all capacitors for corrosion, loose connections, cracks, or signs of breakage should be made. Capacitor mountings should be carefully inspected to discover loose mounting screws, studs, or brackets. Leads must be examined for signs of poor insulation or cracks, and for signs of decay. Frayed strands on the insulation should be cut away.

Variable capacitors should be inspected for any signs of foreign matter lodged between the plates. The operation of the capacitor may be checked by rotating the movable plates.

It is recommended that the plates of variable capacitors be cleaned with a small brush. In no case should the technician use an object that may vary the spacing between the plates.

RESISTORS. —All resistors should be checked for signs of blistering, breaking, chipping, and discoloration. Carefully inspect resistor leads for signs of corrosion, dust, or foreign matter. Resistor leads may become broken at the point of contact with the resistor body. Careful examination will reveal this trouble.

Resistors may be cleaned with a soft brush or a clean, dry cloth. When foreign matter is unusually hard to remove, a suitable authorized solvent may be used. Do not attempt to remove foreign matter from a resistor body by scraping.

FUSES. —Inspect all fuses and fuse holders for evidence of heat and arcing. Usually, burning or overheating will take place when the fuse does not make tight contact with its holder. While fuses are removed, check for signs of corrosion, dirt and foreign matter. When replacing the fuse in the holder, check for loss of tension on replacing the fuse holder cap. Check all wire connections to the fuse holder for tight mechanical and electrical joints.

SWITCHES. —Inspect carefully the mechanical and electrical action of each switch. This is best accomplished by placing the switch in different positions while using your sense of touch, sight, and hearing. Note the freedom of movement and the amount of switch tension in each case. Carefully examine multiple section switches to determine if the contacts are touching and clean. Never attempt to pry wafer

840

contacts apart. All rotary members should make good contact with stationary members on each switch.

Carefully clean all rotary switches with a small brush. Authorized cleaning solvents may be used on contact points when necessary.

POTENTIOMETERS.—Inspect all potentiometers for cleanliness and mechanical action. Potentiometers are protected with dust covers. Do not remove these covers. When evidence indicates that foreign matter exists within the potentiometer structure, send the equipment to a field maintenance activity for replacement activity for replacement of the potentiometer. Examine the potentiometer structure for loose connections and mounting nuts. Use a soft brush or a dry cloth to remove dust and dirt from around the potentiometer.

TERMINAL BOARDS.—Inspect all terminal boards for signs of cracks, dirt, breakage, and loose connections. Check the mounting hardware for the terminal boards. Tighten the mounting hardware securely; when tightening, do not exert too much pressure.

Clean terminal boards with a soft brush. Do not disturb electrical connections unless visual checks show cause.

Check conditions of each wire lead attached to the terminals in the terminal boards. Tighten mechanical connectors and good electrical contact should result.

CONNECTORS AND ADAPTERS.—Inspect the exterior and interior of each connector and adapter. Look for any signs of breakage or cracking. Clean each connector and adapter with a dry, clean cloth.

CABLES AND CORDS.—Inspect carefully all cords and cables for cracked or deteriorated insulation. Frayed or cut insulation around connecting and supporting points is a common type of failure. Examine all insulation for signs of oil and grease.

Clean all dust, dirt, and foreign matter from all cables and cords. Dust and dirt commonly hide defects in cable and cord insulation.

PILOT LAMPS.—Inspect pilot lamp assemblies for loose lamps, loose or dirty connectors, and loose mounting nuts. Inspect the pilot lamp for looseness of the glass envelope. Tighten loose lamps in sockets and clean electrical connections to the pilot lamps socket.

TERMINALS.—Inspect terminals periodically for cleanliness and tightness. When replacing faulty terminal lugs, use only an exact replacement. Clean terminals with a stiff brush; when corrosion is present, use crocus cloth.

CABINET AND CHASSIS.—Inspect the interior of the cabinet for cleanliness. Check the control panel for loose knobs and tighten all loose set-screws on control knobs. Wipe all dust, dirt and foreign matter from the exterior and interior of the cabinet with a clean, dry cloth.

GEARS.—Inspect gear teeth on switch drive mechanisms for cleanliness and ease of operation. Clean drive mechanisms with a small brush. If dirt accumulation is great, use an authorized cleaning solvent.

Corrective Maintenance

Corrective maintenance is performed when an actual trouble exists on the equipment. After the repair has been accomplished, calibration of the equipment is necessary.

The technician is limited to some extent in the corrective maintenance that he is able to perform on test equipments (and still have them function accurately and reliably), principally because he does not have the tools and equipment, and sometimes the spare parts, necessary for this specialized form of maintenance.

REPAIR AND CALIBRATION OF TEST EQUIPMENT

The technician should realize the limitations imposed upon the repair of certain test equipments, and in no case should he attempt repairs until the applicable

841

Service Instruction Manual has been thoroughly read. Particular note should be made of possible circuit misalinement or need for recalibration resulting from parts replacement. In the corrective maintenance section of the test equipment instruction manuals, troubleshooting charts are provided for the localization of trouble. When charts are supplied, they should be utilized for the correction of any trouble.

REPAIR

In repairing a piece of equipment a few preliminary tests, along with a logical procedure, often serve to locate the source of trouble without the use of extensive test equipment. In many cases, the reported symptoms along with a few astute observations will indicate the type and probable location of the trouble. Make observations carefully, and keep the symptoms constantly in mind.

The use of the senses of smell, sight, hearing, and touch often localize the source of trouble rapidly. Note unusual odors, such as sealing compound, which would indicate an overloaded transformer; scorched paint, which could indicate an overheated resistor; and burning rubber, which might point to defective insulation. If any component emits any unusual odor, the trouble might be in that part or in the associated circuit. Examine for smoking parts or sparking. Notice whether wax impregnated capacitors have lost any wax—that is usually indicative of a defective capacitor. Hum, scratch noises, and other odd sounds should have special meaning for the technician, depending upon the type of test equipment that is faulty.

NONSCHEDULED REPAIR OF TEST EQUIPMENT

Naval Air Rework Facilities of naval and Marine Corps Air stations provide a source for "call" type rework or repair to meet nonscheduled requirements. Consequently, depot maintenance activities are prepared to manufacture M series source coded items to satisfy replacement needs for operating units. They are also prepared to perform rework of specific items urgently needed to meet immediate demands where other sources are unable to provide support (usually parts not available or not in stock in supply channels). This type of support is classified as "customer service." Operating activities are encouraged to apply to NARF's in accordance with local command directives for assistance whenever normal support channels have demonstrated an inability to meet demands. Because the capacity for this type of support, in particular, is severely limited by manpower, material, and funds available, units requesting customer service should exercise thorough self-discipline to insure that normal support channels, including the capability of lower levels of maintenance in repair or manufacturing, have been exhausted prior to applying to the depot maintenance facility for assistance. On the other hand, because the capability of each depot maintenance activity is so varied and extensive, it is better to err on the side of requesting service for which no capability exists than to assume noncapability when the service could be performed.

Other support includes disassembly inspections to determine cause for failure or unsatisfactory performance of an individual item and the resultant disassembly inspection reports (DIR's), preservation, in-service repairs, in-service modifications, and related work. This support is controlled by the Naval Air Systems Command Representatives (NavAirSysComRep) within funding and man-hour limitations established by NavAirSysCom.

CALIBRATION POLICY

It is the policy of the Naval Air Systems Command that all test and measuring equipment under its cognizance be calibrated periodically and that participation in the established calibration program is mandatory for all Naval Air Systems Command managed activities and Navy inspection activities.

Fleet, Reserve, and training units, to which NavAirSysCom test equipment is provided for determination of operability and performance of NavAirSysCom material, have the responsibility of insuring that such test equipment is calibrated within the specified periods or exchanged for calibrated equipment. Each NavAirSysComRep provides for scheduling weapon system test equipment, including ready-for-issue avionics test sets, into Navy calibration laboratories under his cognizance. Also NavAirSysComRep stock and issue labels, tags, and

information pertaining to their use and other technical data on the NavAirSysCom calibration program. For further details on the NavAirSysCom calibration program, refer to current instructions.

Complete recalibration of test equipment should not be attempted by the technician. For the most accurate calibration of test equipment, precision meters, frequency standards, etc., must be used. These precision equipments are not usually found in a shop where maintenance of aircraft equipment is performed. Accurate calibration of the equipment requires the more complete testing and calibrating instruments which are available at a test equipment repair facility.

CHAPTER 8

INFRARED DETECTION

Infrared, or IR as it is sometimes called, is assuming increasing importance in missile guidance, target detection, fire control, communications, and mapping. Like radar, infrared was developed and used for military purposes during World War II. Unlike radar, however, the use of infrared has received little publicity. In some military applications, infrared energy has advantages over radar. Infrared, used as a medium of communications, is usually less susceptible to counterdetection and interference than is radar or visible light. Infrared equipment is generally less complex than radar equipment used for similar tasks.

ELECTROMAGNETIC SPECTRUM

IR is a form of electromagnetic energy, with certain characteristics identical to those of light and RF waves. Among these characteristics, some of the more important ones are reflection, refraction, absorption, and speed of transmission. Infrared waves differ from light, RF, and other electromagnetic waves only in wavelength and frequency of oscillation.

The frequency of IR ranges from approximately 300,000 megacycles to 400 million megacycles. Its place in the electromagnetic spectrum (fig. 8-1) is between visible light and the microwave region used for high definition radars. This part of the spectrum is usually discussed in terms of wavelength, and it is generally accepted that the IR spectrum lies between .72 and approximately 1,000 microns (1 micron equals 0.0001 centimeter).

The IR portion of the electromagnetic spectrum is frequently divided into three parts:

1. The near infrared which extends from the visible region out to around 1.5 microns.
2. The intermediate infrared which extends 1.5 to 5.6 microns.
3. The far infrared which extends from 5.6 microns to microwave frequencies.

Some confusion in terminolgy exists because infrared energy is so close to the visible range of wavelengths in the electromagnetic spectrum. Thus it is not uncommon to hear references to "infrared light," although the term is inaccurate. Infrared waves are also loosely referred to as heat waves, because of the well-known fact that a solid object subjected to radiation by infrared energy undergoes an increase in temperature. Heat differs from infrared waves in much the same way that electricity differs from radio waves.

INFRARED RADIATION

All objects above absolute zero (0° K or -273° C or -460° F) emit infrared radiation. Radiation from any given object is emitted over a wide range of wavelengths, but it peaks at one particular wavelength. This point is of considerable interest in military applications, as will be shown later. Detection of infrared energy depends on the contrast between IR from the source under consideration and the radiation emitted by the background. A cold object with a warm background has just as good target definition as a warm object with a cold background.

There are a number of advantages in using IR for target detection rather than some other form of electromagnetic transmission. Among these are:

1. IR systems are passive.
2. Although IR systems can be confused, complete jamming is just about impossible.
3. Military targets are usually good sources of IR.
4. IR systems may be made smaller, lighter, less complex, and less expensive than other comparable systems.
5. IR systems have higher resolution.

EMISSIVITY

One of the most useful concepts employed when working with IR is the "black body." A black body is defined as an object which absorbs

844

Figure 8-1.—Electromagnetic spectrum, showing different wavelength units used in different bands of the spectrum.

all radiation incident on it. Conversely, the radiation emitted by a black body is the maximum possible for any given temperature. This black body is then a perfect absorber and radiator of IR at all temperatures and for all wavelengths.

In order to compare the radiation emitted by an actual source with that of a perfect radiator, the concept of emissivity is employed. Emissivity is defined as the ratio of the total radiation emitted by any object at a temperature T to the total radiation which would be emitted by an ideal black body at the same temperature. The emissivity of any object depends on the amount of energy its surface can absorb. If the surface absorbs most of the IR striking it,

845

then it will emit a relatively high amount of radiation, and the emissivity of the object will be comparatively large. By the same reasoning, if the surface reflects most of the incident radiation, the object will have a relatively small emissivity. By definition, a black body has an emissivity of unity. Therefore, any other object will have an emissivity of less than one. Table 8-1 shows the emissivity of various surfaces.

Table 8-1.—Emissivities of various surfaces.

Surface	Emissivity
Black body	1.00
Lampblack	0.95
Painted	0.90
Steel, cold-rolled	0.60
Aluminum paint	0.25
Steel, stainless	0.09
Aluminum aircraft skin	0.08
Aluminum foil	0.04
Silver mirror	0.02

Laws of Emissivity

The basic laws which describe the characteristics of IR were developed first for black body radiation, the ideal case, and then modified to describe the radiation from any source.

The most important parameter in determining the IR characteristics of any body is its temperature. As the temperature of an object changes, two specific changes in the IR characteristics take place: The wavelength where peak radiation occurs is shifted, and the total energy radiated varies with the fourth power of the temperature. These fundamental relationships are given by two laws which are discussed in the following paragraphs.

WIEN'S DISPLACEMENT LAW.—This law states that the wavelength at which maximum radiation occurs, λ_m is inversely proportional to the absolute temperature of the body. This can be expressed by

$$\lambda_m = \frac{K}{T}$$

where the wavelength is given in microns, and the constant (K) has a value (for a black body) of about 2,900. For example, a block of ice emits its peak energy at about 10 microns, while energy emitted from a jet aircraft engine peaks at about 3.5 microns. The relationship is shown in figure 8-2.

STEFAN-BOLTZMANN LAW.—This law states that the radiation intensity, E, is directly proportional to the fourth power of the absolute temperature, experessed as

$$E = \sigma T^4$$

where E dimensions of power per unit area, and σ has the proportionality constant. In other words, if the temperature of an object is doubled, the radiation emitted from the object will be 16 times as much.

The Stefan-Boltzmann Law can be modified to include emissivity factor, and by using the right units, the total radiation can be obtained by

$$E = \epsilon \sigma T^4$$

where ϵ is the emissivity factor of the radiating surface.

A black body at an absolute temperature of 300° (81°F) will radiate 46 milliwatts of power per square centimeter of its surface. A painted surface such as the skin of a commercial airliner, at the same absolute temperature will radiate 41 milliwatts per square centimeter. If this aluminum aircraft skin were not painted, the emissivity factor would be considerably smaller, and the radiation would be less than 4 milliwatts of power per square centimeter.

As mentioned previously, IR from a source will be distributed over a good part of the spectrum, but the maximum radiation occurs at some specific wavelength. Figure 8-3 shows the distribution of energy radiated from a black body at various temperatures.

As an example, IR from jet and rocket engine exhaust plumes is primarily due to the molecular excitation of water vapor and carbon dioxide which are characteristic byproducts of combustion. This molecular radiation peaks at 2.7 microns (due to water vapor and carbon dioxide) and 4.3 microns (due to carbon dioxide alone). In a practical situation, however, more usable radiation is obtained from the hot tailpipe and other heated surfaces.

Figure 8-2. —The wavelength of the peak radiation from a black body in relation to its temperature.

847 31,888

Figure 8-3.—IR distribution curves for a black body at various temperatures.

TRANSMISSION CHARACTERISTICS

In military applications of IR systems, the transmitting medium is generally the atmosphere. The effect of the atmosphere on the transmission of IR is a very important factor in considering the overall effectiveness of the system.

Atmospheric Absorption

There are two primary causes of atmospheric attenuation: scattering by suspended solids, and absorption by free molecules. These two influences on the attenuation are additive, but the absorption is the most important factor.

The amount of scattering caused by particles depends on the relationship between the wavelength of the radiated energy and the size of the particles. If the wavelength involved is considerably shorter than the dimensions of the particles, then the scattering is just about independent of wavelength. Since this is generally the case in the IR spectrum, the attenuation due to scattering can be measured at one wavelength and then applied over a relatively wide band of wavelengths.

This technique does not work, however, with attenuation due to molecular absorption. The amount of absorption is closely connected with the wavelength. The two substances in the atmosphere which absorb the most radiation are water vapor and carbon dioxide. In both of these substances, there are several wavelength bands where the absorption is relatively large. This condition is caused by molecular resonance. (Each molecule has a "natural frequency" of vibration, or resonant frequency.)

The resonant frequencies of these molecules are in the infrared region, and their structure is such that this natural vibration creates an oscillation of electric charge in the molecules which increases the absorption. At low altitudes, where the atmosphere is more dense, this absorption is so great that in some wavelength bands the percentage of radiation transmitted drops rapidly to zero. Between these absorption bands are areas where the atmospheric attenuation is not so great. These transmission bands are called "windows." The transmission windows in the atmosphere are approximately as shown in table 8-2.

848

Table 8-2.—Wavelength limits of IR transmission windows in the atmosphere.

0.95	-	1.05	microns
1.2	-	1.3	microns
1.5	-	1.8	microns
2.1	-	2.4	microns
3.0	-	5.0	microns
8.0	-	12.0	microns

Figure 8-4 shows the transmission characteristics of the atmosphere at two different altitudes. It will be noted by reference to figure 8-4 that the 2.7 and 4.3 micron radiation readings from a jet exhaust plume occur at frequencies of high absorption. The radiation resulting from hot tailpipe surfaces is a function of tailpipe material and temperature, usually peaking at about 3.5 microns. This frequency is in the region of an atmospheric window or low absorption band. It will also be noted that the absorption bands are much narrower at high altitudes due to the thinner atmosphere. These absorption bands will, therefore, be of lesser consideration in the design of high altitude systems.

Optics

Optical devices based on equipment similar to that used in visible light systems are employed to collect and focus IR on a detector. A simplified focusing system, as shown in figure 8-5, would consist of a protective housing, an IR dome, and a lens. The housing is used to protect the detector and optics from the weather. The radiation enters through the dome, which is a hemispherical continuation of the protective housing. The dome must be transparent to IR. Materials such as optical glass, quartz, synthetic sapphire, rock salt, germanium, and silicon are used in making the dome. (Ordinary window glass is opaque to waves in the far infrared region.)

There are a number of problems involved in the design of IR optical systems. The material used must match the wavelength to which the detector will respond. Optical materials are generally weak physically, and many have a low resistance to high temperature and thermal shock. Chemical reactions and pressure will change the properties of some materials.

Another vital problem is that of system heating. If any part of the system becomes heated by energy is has absorbed, this energy will be reradiated at wavelengths that differ from those of the original radiation. If the detector is sensitive to these new wavelengths, this source

Figure 8-4.—Atmospheric transmission characteristics.

Figure 8-5.—A simple IR optical system.

which is much closer than the target will obscure the target or cause "ghost" images.

Attenuation in optical materials is primarily due to two things: surface reflections, usually overcome by antireflection coatings; and attenuation by the material. The latter is the more serious problem.

IR systems often have a chopping reticle in the principal focal plane. The chopper is generally a rotating disk with some clear and some opaque areas. Although a chopper is not absolutely necessary in a search system, it has several useful properties. The chopping rate furnishes a conveniently high carrier frequency for the electronic amplifiers. The reticle pattern can operate as a discriminator or filter. For example, it can be designed for the type of backgrounds expected in order to provide better differentiation of target and background.

Optical filters are used in IR instruments to isolate certain wavelength regions of interest, such as atmospheric windows, and to screen out undesired wavelengths. Three general types of filters are:

1. Those which pass short waves.
2. The bandpass type.
3. Those which pass long waves.

DETECTORS

The most critical component of any IR system is the detector. The characteristics of the atmosphere and the source, if it is a military target, cannot be changed. Optical materials are somewhat standardized, as are display devices and control circuits. Although research and development in the last decade has resulted in some very good all-round detectors, it is still necessary to use care in choosing the proper one for a particular application.

Many variables must be considered in the choice of a detector. The characteristics of the radiation involved will determine which type of detector will best fit the need of the system.

DETECTOR CHARACTERISTICS

In order to compare the relative merits of different detectors in different situations, it is necessary to introduce several parameters of detector operation. These parameters make it possible to discuss the characteristics of a particular detector in terms which can be applied to any detector.

Responsivity

When IR strikes a detector material, either photoelectric or thermal, a change takes place which produces an electrical output signal, indicating that the material has been irradiated. The amount of signal produced by each unit of input radiation intensity is called the responsivity of the detector, and is expressed as

$$R = \frac{\text{output}}{\text{input}}$$

generally in volts per watt. Many factors influence the responsivity, such as temperature of the detector and source, detector area, spectral distribution of the radiation, detector time constant, etc.

Spectral Response

One important influence on the responsivity of a detector is the change in detector sensitivity with changes in the wavelength of received radiation. The spectral limit of responsivity is considered to be the wavelength where the responsivity is half that of its maximum value. Since the spectral response is a nonlinear characteristic, it must be known for each wavelength considered, and any discussion of values must include the details of the conditions involved.

Time Constant

In any IR scanning system, the time constant of the detector must be such that the detector can fully respond before the radiation intensity changes. The time constant is considered to be the time required for the detector to develop 63 percent of its maximum output signal. The

maximum scanning rate is dependent upon this time constant.

Noise

Many different types of noise are generated within IR systems. Among these, the most important are:

1. Current noise, caused by bias currents within the detector.
2. Johnson (thermal) noise, caused by thermal fluctuations in the detector material.

At low bias voltages, current noise is negligible and the output noise voltage consists almost entirely of Johnson noise. The current noise increases linearly with bias voltages and may eventually become the primary source of noise.

NOISE EQUIVALENT POWER. —Another useful and important detector parameter is the noise equivalent power (NEP) of a detector. NEP is the radiation power in watts which must strike a detector to produce a signal response from the detector equal to the noise output (in other words, signal to noise ratio of 1) over a reference bandwidth.

When comparing two different IR detectors, the one with the lower NEP has the higher useful sensitivity. Since this tends to be confusing, another parameter is used: the detectivity. This figure is simply the reciprocal of the given NEP of a detector, so that the higher detectivity a cell has, the higher is its useful output. For example, a detector with an NEP of 4.0×10^{-9} will have a detectivity of 2.5×10^{-8}.

The best IR detector would be one having the greatest possible responsivity, the widest possible spectral response within the frequency band of interest, and the lowest possible NEP (or highest possible detectivity). A properly chosen detector, with the necessary operating conditions, might have a maximum range of 90 miles with a signal to noise ratio of 5 from a 1 square meter target at 300 degrees Kelvin. This range is equivalent to an ability to detect IR emitted by a cubic inch of ice at 3 miles.

PHOTODETECTORS

The three major types of photodetectors are photoconductive, photovoltaic, and photoemissive detectors. Signal to noise ratio of the detector is the limiting factor in determining its effectiveness. These are used in the near infrared spectrum.

Photoconductors use a semiconductor crystal that absorbs the photon energy from the radiation which strikes the surface of the crystal, changing its resistance or conductivity. Quite a number of materials have been used for this type of photodetector, including lead sulfide, lead telluride, lead selenide, cadmium sulfide, and many others. Gold-doped germanium has been established as a good detector material, but some difficulties, such as the long time constant, must be considered.

Photovoltaic cells are similar to solar cells. These are semiconductors with a high resistance photosensitive barrier between the two layers. When exposed to IR this cell builds up a potential difference between the two layers.

Photoemissive cells operate on the principle that electronic emission is caused by exposing the cathode to IR. In this type of emission, the number of electrons emitted depends on the intensity of the IR striking the cathode.

THERMAL DETECTORS

Thermal detection is accomplished by sensing the change in temperature of the detector material as a result of IR striking its surface. There are three different types of sensing elements employed in modern detectors to sense this temperature change. These are as follows:

1. The thermopile, which is a series combination of several thermocouples.
2. Bolometers, which sense the change in resistance of the detector material.
3. Pneumatic cells, which use the expansion of a gas as an indicator.

Thermocouple

One of the basic heat detectors is the thermocouple. When two dissimilar metals such as iron and copper are joined together and heat is applied to the junction, a measurable voltage will be generated between them. Figure 8-6 shows a basic thermocouple.

The voltage difference between two metals is quite small, but the sensitivity can be increased to a point at which the thermocouple becomes useful as a detector of IR. The increase in sensitivity is obtained by connecting or stacking, a number of thermocouples in series, so that they form what is known as a thermopile. The complete thermopile action is similar to that obtained when a number of flashlight cells are connected in series. That

Figure 8-6. —Thermocouple.

is, the output of each individual thermocouple is added to the output of the others. Thus, ten thermocouples, with individual output voltages of 0.001 volt, would have a total output of 0.010 volt when connected in series.

The effecitve sensitivity of a thermopile can be further increased by mounting it at the focal point of a parabolic reflector. When this method is used, IR given off by the target is focused on the thermopile by the reflector.

Bolometers

A bolometer is a very sensitive material whose resistance will vary, depending on the amount of IR to which it is exposed. There are two main classes of bolometers—barretters and thermistors.

A barretter consists of a short length of very fine wire (usually platinum) which has a positive temperature coefficient of resistance. (A resistance has a positive temperature coefficient if its value increases with temperature, and a negative coefficient if its value decreases with an increase in its temperature.)

The thermistor is a type of variable resistor made of semiconducting material, such as oxides of manganese, nickel, cobalt, selenium, and copper. The thermistor has a negative temperature coefficient of resistance. Thermistors are made in the form of beads, disks, rods, and flakes, some of which are shown in figure 8-7.

The heat sensitive materials of thermistors are mixed in various proportions to provide the specific characteristics of resistance versus temperature necessary for target detection.

Figure 8-8 shows the change in resistance which can be produced in a typical thermistor material and in a barretter. This comparison shows that the thermistor has the steeper temperature coefficient of resistance curve, and therefore is the more sensitive of the two sensors.

One simple type of infrared detector consists of two thin strips of platinum which are used to form two arms of a Wheatstone bridge. To increase the thermal sensitivity of the strips, each is blackened on one side. The IR to be measured is applied to one of the strips, and is absorbed by its blackened surface. As the strip absorbs heat, its resistance changes and unbalances the bridge. The imbalance causes a change in the current produced by an external voltage applied to the input terminals of the bridge.

A device of this kind is shown in figure 8-9. It consists of four nickel strips supported by mounting bars, which have electrical leads attached to them. A silvered parabolic reflector (mirror) is used to focus the IR on the nickel strips. The change of resistance in the strips produces unbalanced conditions in the bridge circuit which can be used to produce correction signals.

Pneumatic Cell

Another unique infrared detector is the pneumatic cell or GOLAY detector shown in figure 8-10. This detector is actually a miniature heat engine.

Infrared energy entering the window causes expansion of a volume of gas located between the reflecting diaphragm and the window. The lamp at the after end of the detector emits a light beam which is focused by the lens and then passes through the grid and onto the reflecting diaphragm. The expansion and contraction of the gases between the window and diaphragm will cause the diaphragm to change its shape in response to changes in the amount of infrared energy entering the window.

Changes in shape of the diaphragm will cause its light-reflective properties to vary accordingly, modulating its light output. The light reflected from the diaphragm will then pass back through the grid which is designed to intensify the variations of the reflected light. After passing through the grid, some of the light strikes the mirror and is reflected to a photocell of high sensitivity (not shown in the

852

Figure 8-7. —Various thermistors.

figure). The modulated output of the photocell is a voltage proportional to the intensity of the IR entering the window.

The Golay detector has the most rapid response of any infrared detector, but it can operate only when radiant heat is received intermittently. An optical chopper may be used to interrupt the flow of IR to the cell periodically. Another advantage of the Golay detector is its extremely wide bandwidth, making it a very good choice for use in IR spectrum analysis.

APPLICATIONS

Military and industrial applications of IR have grown in number considerably in the last decade. A complete discussion of all applications would be beyond the scope of this course. However, some of the systems and concepts applicable to military situations are discussed in the following paragraphs.

MILITARY USES OF INFRARED

Infrared devices found their first military uses during World War II as a snooperscope which operated in total darkness and outlined enemy troops by the heat radiated from their bodies. A rifle with a device known as the sniperscope made it possible to see a target in total darkness and fire with normal accuracy without the enemy's becoming aware of one's presence.

Since infrared is invisible but behaves much like visible light, that is, it can be reflected and controlled in a beam pattern, it has served as a means of communication for specific wartime purposes. Development of equipment which would receive the invisible light was the foundation for the design and successful use of some highly important weapons. Infrared, when used for short-range communication between sea-level stations, such as ships, affords excellent security. Infrared rays are limited to line of sight, and are rapidly attenuated at sea level; thus, IR acts in favor of security for short-range communications. Military use of infrared for communications therefore requires a powerful source that can be modulated, and sensitive receivers for detecting the modulated source. Such sources and receivers have been developed for near infrared energy.

853

Figure 8-8.—Comparison of thermistor and barretter sensitivity.

Figure 8-9. —Infrared detecting device.

Figure 8-10. —Golay detector.

Infrared is used in photography as it is effective against camouflaged targets. Night photography using infrared can produce a better visual presentation of terrain than the best mapping radar.

Infrared has invaded the navigation field. Groundspeed indicators are being developed that will compete with Doppler radar. Anticollision circuits are under experimentation.

IR is also used in image forming devices, thermal or ship detection, and infrared radar. The portable infrared detector (PND) is a passive far infrared equipment used for the detection of personnel, vehicles, tanks, small boats, and ships. It detects the difference in temperature between a body and its immediate background and provides an audible signal output. A larger far infrared system for ship detection is the stabilized ship detector. This provides a permanent record of the true bearing of all targets that are detected within the angle scanned. Infrared radar uses a pulsed IR source and receives reflected IR energy as in microwave radar.

Infrared has excellent application to guided missiles. Military targets, such as ships, factories, and aircraft, are normally warmer than their surroundings. The presence of these targets may be detected by the heat radiation they emit. The radiation of heat at lower temperatures is particularly important in the passive detection of surface targets, since there is no economical way by which the enemy can camouflage his self-radiated heat.

The Felix bomb was the first guided missile to utilize IR. It was automatically guided by an infrared homing device in the nose of the bomb. The Felix bomb was thoroughly tested and declared reliable and adequate for operational use, but World War II ended before it could be used under combat conditions. This opened the way to a new and different method of guidance, infrared homing.

Homing guidance systems control the path of the missile by a device in the missile that reacts to some distinguishing feature of the target. They are the most accurate of all guidance systems. Homing systems are divided into three types, depending upon the source of target radiations:

1. Active homing—both the source which illuminates the target and the receiver which detects the echoes are carried in the missile.
2. Semiactive homing—the target is illuminated by some source outside the missile and the missile receiver utilizes the target reflections.
3. Passive homing—the missile receiver detects the natural radiation of the target.

Active and semiactive types generally use radar, whereas passive types use heat, light, or in some cases, home on a radio or radar transmitter.

The Sidewinder is probably the simplest and cheapest of all guided missiles. It uses an infrared homing system and is designed to destroy high-performance aircraft from sea level to about 50,000 feet.

The experimental Midas satellite, which was launched by the United States, employs infrared principles. It is equipped with an infrared scanning device capable of instantaneous spotting and reporting of the launching of a hostile ballistic missile. It is expected to provide complete and constant scanning of the earth's surface. By flashing the alarm of the blast-off of enemy missiles, they would give the United States 30 minutes to prepare for nuclear bombardment.

While it is unlikely that radar will ever be entirely replaced by IR, it is already an established fact that IR possesses certain advantages over radar. It is expected that radar and IR will work as a team in many applications, such as fire control, guidance, and even search. There is no known method by which infrared can be jammed.

856

CHAPTER 9

MAGNETIC AMPLIFIERS

The magnetic amplifier combines many of the advantages of both the vacuum tube and the thyratron and in addition contributes several of its own characteristics to advantageous uses in handling large amounts of power. Although its ability to control large amounts of power is an important feature, it is also well suited and frequently used in devices involving signal or voltage amplification. It is usually necessary or desirable to add control currents from several different sources. This is easily accomplished by putting additional windings on the magnetic amplifier core.

Many different trade name devices, such as self-saturating magnetic amplifiers, Magamps, Transductors, and Amplistats, have been used to identify the more elaborate saturable reactor circuits. However, the term magnetic amplifier is used in this chapter to identify all amplifying systems which utilize the saturation of a magnetic core for the purpose of control, It is felt that this is the most popular of all terms used at the present time.

The advantage of the magnetic amplifier is principally based on the fact that it is a completely static device. With the exception of the rectifiers used, its mechanical construction is comparable to that of an iron core transformer. There are no contacts, moving parts, filaments, or other features which account for most of the failures associated with other types of amplifiers (except for those using transistors). The need for frequent inspection and maintenance is cut to a minimum. The life of the magnetic amplifier is more or less indefinite, and it is especially suited for aircraft installation where there are adverse operating conditions such as vibration and shock.

In order to understand the theory of magnetic amplifiers, a knowledge of magnetism and magnetic circuits is necessary. This information may be found in chapter 7 of Basic Electricity, NavPers 10086-A. In addition, chapter 18 of Basic Electricity discusses the basic principles and materials found in magnetic amplifier usage. These subjects are reviewed here only to the extent necessary for continuity. It is the intent of this discussion to build upon these basic considerations and develop the subject of magnetic amplification in greater detail.

BASIC MAGNETIC AMPLIFIER

The basic circuit for controlling the load power by means of a control winding is illustrated in figure 9-1. Both windings are on a common core; the primary is usually referred to as the control winding.

The primary winding is supplied with a d-c source for control purposes. A potentiometer is connected in series with this circuit and is used to control the amount of current flow.

This current will establish a unidirectional flux in the core at a level depending upon the amount of d-c magnetizing force. The second winding is connected in series with an a-c source and the load, which is shown as a lamp.

Changes of current through the control winding correspond to variations in magnetic field intensity (ampere turns). (See fig. 9-2.) These variations over the portion of the curve between the origin and point a will produce little or no change in inductance or permeability due to the nearly straight characteristic of the curve. In order for these changes in current to produce changes in inductance, they must take place on the curved portion, or knee of the curve. This means that sufficient current must flow through the control winding to place the operating point at the knee, such as at point c. This is very similar to setting the operating point of a vacuum tube by means of bias.

With the coil operating on the knee of the magnetization curve, a small increase of current through the control winding will lower the inductance of the coil, or permeability of the

857388

Figure 9-1. —A basic magnetic amplifier.

core, because the magnetization curve's slope is moving toward a horizontal direction. As a result, the a-c reactance of the load winding is decreased. The decreased impedance of the load circuit will then allow a larger current to flow, thereby increasing the power developed across the load. With the core completely saturated, the load winding reactance drops to nearly zero, leaving only the resistance of the copper wire to impede the flow of current. Under this condition, the maximum supply voltage will be applied to the load; thus the lamp will be brightest. Conversely, decreasing the current through the control winding will increase the reactance of the load coil, thereby decreasing the power developed across the load.

In the region between the origin and point a on the curve in figure 9-2, the core permeability (hence coil inductance) is maximum, resulting in minimum load current and, consequently, minimum output power. Since the reactance of the load coil winding has been changed by varying the degree of core saturation, the device is referred to as a saturable reactor. The following rule will apply to any saturable reactor or magnetic amplifier: A control current which tends to saturate the core will increase the output of the amplifier.

Figure 9-2. —Magnetization and permeability curves.

IMPROVED MAGNETIC AMPLIFIER

The basic magnetic amplifier circuit shown in figure 9-1 is very inefficient because of transformer action between the two windings. The alternating flux from the secondary will induce a voltage into the primary control winding. If the control winding has a large number of turns, the voltage may become excessive and may even break down the insulation.

Another reason why this form of magnetic amplifier is seldom used is the fact that the control winding would act as a short circuited secondary. This would dissipate a considerable amount of a-c energy that is applied to the control winding. It is possible to prevent this loss by inserting an isolating impedance, in the form of an inductance, in series with the control winding. Another method of preventing this loss is by utilizing a three-legged core. This and other circuit improvements are discussed in the following section.

BASIC CIRCUITS

The transformer action previously mentioned would also cause an oscillating flux in the core and the usual B-H hysteresis loop of the core material would be traced out during one full-cycle of the a-c source voltage as in transformer operation. In order for this circuit to function as an amplifier, sufficient d-c magnetizing force is required to counteract the a-c flux, and an additional amount of d-c magnetizing force is needed to set the operating point.

THREE-LEGGED CORE

A much more satisfactory arrangement for a saturable reactor is shown in figure 9-3. This figure shows a three-legged core having an a-c winding on each outer leg connected in series and the d-c control winding on the center leg. In the center leg of a saturable reactor of this type, any alternating flux produced by one of the a-c coils is balanced by the flux produced by the other a-c coil. This is true only when both a-c coils have an equal number of turns and are connected either in series or parallel

Figure 9-3. —A magnetic amplifier with three-legged core.

such that the flux fields produced by the two coils oppose each other through the center leg. This is shown by the dotted lines in figure 9-3.

Since these forces are opposite and equal, they do not pass through the center leg but join in a common path through the outer legs of the core. This is shown by the broken lines in figure 9-3. The figure also shows that the current through the d-c winding on the center leg of the core produces a magnetic flux as indicated by the arrows on the solid lines. The flux lines are caused by the direct current flow in two paths, as shown, and magnetize the entire core. Although the d-c coil is used to magnetize the cores of the a-c coils, no a-c voltage is induced into the control coil when a three-legged reactor is used.

During operation, variation of current in the control coil will vary the magnetization of the core. As has been shown previously, when the magnetizing force is altered, the permeability of the core is varied and, in turn, the inductance of the a-c coils is also varied. In other respects the three-legged magnetic amplifier functions similar to the basic circuit.

As mentioned previously, the a-c coils can be connected either in series or parallel. The series connected a-c coils offer the advantages of higher voltage gain and faster response characteristics. The parallel connected a-c coils are capable of handling loads with medium to high current consumption as may be required by large servomotors. The time of response is longer for the parallel windings.

Half-Wave Amplifier

Another improvement to the basic magnetic amplifier is the use of half-wave rectifiers. Chapter 18 of Basic Electricity, NavPers 10086-A, contains a circuit which includes their application. However, the discussion which follows is fundamental to magnetic amplifier circuits as found in aviation electronic equipment.

The type of magnetic amplifier shown in figure 9-1 is relatively inefficient. This is true because the load supply voltage, which is alternating, will create a sinusiodally varying flux which will flow through the core in one direction during one-half of the cycle and in the opposite direction during the other half. Thus, half of the time the flux created by the load current will impede the d-c control winding flux and the other half of the time it will aid this flux. This will shift the operating point of the amplifier from the origin (fig. 9-2) to a point of the curve whose abscissa (horizontal coordinate) corresponds to the peak value of ampere turns, back to the origin, and along a similar curve in the negative direction. In other words, the operating point of the amplifier will trace out a hysteresis curve such as is shown in figure 9-4. Because the amplifier cannot operate in this manner, the oscillating flux must be bucked or counteracted and then a directional flux must be added to partially saturate the core or place the operating point on the desired portion of the magnetization curve.

In order to produce sufficient flux to balance out the oscillating flux caused by the alternating current in the load winding, the ampere turns applied to the control winding would have to equal the ampere turns of the load winding. Then sufficient extra ampere turns would have to be applied to the control winding to set the operating point at the desired place on the magnetization curve. It is obvious then that this would be a very inefficient amplifier because the ampere turns required by the control loop would be greater than the ampere turns in the load circuit.

Figure 9-4. —Hysteresis loop.

A more efficient magnetic amplifier utilizing internal feedback is shown in figure 9-5. A half-wave rectifier has been inserted in the load circuit allowing current to pass in one direction only. This unidirectional load current eliminates the oscillating flux caused by the alternating current in the load circuit. Thus, the load current assists the control winding current in saturating the core. A more efficient amplifier is thus provided since less control power is needed for a given amount of control. In this figure the control circuit is so arranged that the magnetic flux resulting from the control current may either aid or oppose that resulting from the load current.

Figure 9-5. —Magnetic amplifier with half-wave rectifier.

A brief explanation of the self-saturating half-wave magnetic amplifier is possible by using the magnetization curve shown in figure 9-6. This curve has been drawn with the effect of hysteresis neglected. Position a on this curve represents the condition of the control flux when the potentiometer in figure 9-5 is set at the positive end. Under this condition the control current produces a flux which is in opposition to the flux created by the load current. If the amplitude of the alternating current is such that it varies the core flux along the magnetization curve from point a to point d, the impedance of the secondary remains large and the voltage drop across the load will be approximately zero.

The relation of the applied voltage and load current for this type of operation is represented by a in figure 9-6 (B). When the potentiometer is moved toward the negative end to the position where current still flows in the same direction but of less amplitude so that the control flux is at point b on the curve, the rectified alternating current will now vary the core flux from point b to point e. Under these conditions partial saturation of the core is achieved, resulting in a low voltage waveshape as shown at b in figure 9-6 (B). As the potentiometer is moved further toward the negative end, the initial flux density in the core (no load winding flux) is nearer saturation so that the inductance of the controlled winding is reduced earlier in

Figure 9-6. —Operation of a self-saturating magnetic amplifier.

860

the half-cycle and larger values of load current flow. This is shown by c, d, and e in figure 9-6 (B).

Using Bias for Flux Reset

When the core material possesses hysteresis properties that produce a rectangular shaped B-H curve, it may be necessary to bias the core in order to retain control. This is accomplished by allowing a bias current to flow either through the control winding or through a separate bias winding. This bias current provides a means of resetting the flux to the initial operating point during the control period. Thus, no control current is necessary to reset the flux. Figure 9-7 shows a separate bias winding wound on the center leg of a three-legged core.

The core is usually biased so that with zero control current the load winding flux saturates the core midway in the operation cycle. This bias setting enables the control current to either advance or delay the point of saturation. In other words, if the polarity of the control current is such that the flux produced by it adds to the bias flux, the point of saturation will be delayed. (Control and bias flux are in opposition to load winding flux.) A control current of opposite polarity will produce a flux that opposes the bias flux and this will advance the point of saturation.

The bias may be either alternating or direct current. In most cases the polarity of d-c bias is such that it opposes the load current flux. The magnitude of the bias might be such that it would reset the flux to a point between a and c figure 9-2. There are some applications where the opposite is true: in these applications the purpose of the bias is to provide an initial d-c saturation in the core in order to obtain greater amplification of weak signals.

Full-Wave Amplifier

The magnetic amplifier that has already been discussed produces a pulsating or half-wave output. In most applications of magnetic amplifiers, full-wave operation is more desirable for it is more efficient since the load is energized during both halves of the a-c cycle. Full-wave operation may be obtained by using a pair of simple half-wave magnetic amplifiers operating in parallel. A typical circuit arrangement is shown in (A) of figure 9-8.

The load current is controlled by means of two control windings connected in series. Each amplifier unit contains a rectifier so that load current flows alternately in the two amplifiers. As one conducts, the core of the series coil in the other is being set by the action of the control current. And with each amplifier conducting during approximately one-half of each cycle of load current, the output variations are full-wave in nature.

Output waveforms for two different control currents are shown in (C) and (D) of figure 9-8. The waveform in (C) is produced when the control current biases the core near the point of saturation. In this condition, saturation of the magnetic cores of the amplifiers is reached

Figure 9-7. —Bias winding.

Figure 9-8. —Full-wave magnetic amplifier and output waveforms.

861

early in each half-cycle, and the resulting output current variation are almost sinusoidal in shape.

When the current in the control winding biases the core in such a way as to produce the waveform of figure 9-8 (D), the average value of load current is considerably less than when the control current biased the core to near saturation. Thus, as in the half-wave circuit, the output power developed in the load can be varied by controlling the load current. The output that is developed is an alternating current and is in phase with the source voltage. Figure 9-8 (B) shows a magnetic amplifier that functions similar to the one shown in (A). The major difference is that the two cores shown in (A) have been combined to form a three-legged core.

CROSSOVER WINDINGS

In discussing the theory of operation of the full-wave magnetic amplifier circuits shown in figure 9-8, it was assumed that the rectifiers have zero forward resistance and infinite back resistance. In actual practice this assumption is not valid since rectifiers do not have infinite back resistance. It should be apparent that any back current flowing through the rectifiers shown in figure 9-8 (A) during their nonconducting half-cycle, will produce a magnetic flux which will tend to drive the core out of saturation. During the conducting half-cycle, a part of the load current would be absorbed in bringing the core back to the point of saturation, thus reducing the gain of the amplifier.

One method of counteracting this effect is by the addition of a crossover winding to the two magnetic amplifier cores. Figure 9-9 illustrates a magnetic amplifier utilizing full-wave rectification and crossover windings. It should be noted that this circuit is similar to the circuit shown in figure 9-8 (A) with the addition of the crossover windings.

Figure 9-9. —Full-wave magnetic amplifier utilizing crossover windings.

The crossover winding consists of a few turns which produce a magnetic field in a direction opposite to that produced by the backward current through the load winding. Referring to figure 9-9, consider the action of the load and crossover windings on the two cores. Assume that during the first half-cycle of the a-c supply voltage, rectifier 1 is conducting in the forward direction. The heavy current, flowing through rectifier 1 and the load winding on core 1, also flows through the crossover winding of core 2. During the same half-cycle a small backward current is flowing through rectifier 2, the load winding on core 2, and the crossover winding on core 1. This small backward current, flowing through the large number of turns in the load winding, produces a magnetic field that is canceled by the heavy current flowing through the small number of turns of the crossover winding on core 2. A similar cancellation is achieved on the second half-cycle of the a-c supply voltage by the other crossover winding.

Since the back resistance of the rectifiers will vary with temperature and applied voltage, some means must be provided to insure cancellation of the field resulting from the backward current at all times. A small constant resistance, R_S, is connected in parallel to the high, but variable, back resistance of the rectifiers. Each rectifier is shunted during its nonconducting half-cycle by the series combination of R_S and the conducting rectifier. The variations in the back resistance will now have no noticeable effect on the quantity of backward current through the load windings.

EXTERNAL FEEDBACK

It is possible to change some of the characteristics of a magnetic amplifier by the use of external feedback. (NOTE: The action of rectifiers in series with the load current discussed earlier in this chapter constitutes internal feedback.)

Feedback is the returning of a portion of the output of an amplifier stage to the input of that stage or a preceding stage and may be either positive or negative depending on the effect desired. It has the effect of adding to or subtracting from the flux density created by the control

circuit current. Regenerative or positive feedback, which increases the control circuit flux density, makes the circuit more sensitive to changes in control current; thus, the power gain of a single stage may reach 40 to 50 db. However, this type of feedback has two disadvantages for it increases the time lag characteristics of the amplifier, and may also cause instability. Degenerative or negative feedback reduces the gain of the amplifier by decreasing the flux density created by the control winding current; however, it increases the linearity of the magnetization curve and reduces the time lag characteristics of the amplifier.

The curves in figure 9-10 illustrate the effect of both positive and negative feedback on load current as a function of input control current. It should be noted that the same amount of direct current is needed to saturate the core regardless of the amount of feedback provided. However, when using positive feedback, less input control current is required to saturate the core since the feedback current aids the control current toward this end. The gain characteristics of magnetic amplifiers with positive and negative feedback may be compared by studying the curves shown in figure 9-10. The following should be concluded:

1. Output current is the same when saturation is attained regardless of feedback.
2. Linearity and stability improve with degenerative (negative) feedback.
3. Gain improves with regenerative (positive) feedback.

A schematic diagram of two magnetic amplifier circuits utilizing external feedback is shown in figure 9-11. Feedback is provided by an additional winding on the center leg of each core. The direct current flowing through the feedback

Figure 9-10. —Effects of external feedback.

Figure 9-11. —Magnetic amplifiers using external feedback.

winding creates a magnetic field which either aids or opposes the magnetic field created by the control current.

In (A) of figure 9-11 the a-c load current is rectified prior to being fed through the feedback winding. It should be noted that the feedback current consists of the total load current and it will always flow in the same direction regardless of the input signal. To change the feedback from regenerative to degenerative or vice versa, the feedback winding connections must be reversed.

Figure 9-11 (B) illustrates the use of external feedback in a magnetic amplifier supplying a d-c load. The amount of feedback is controlled in both circuits by setting of the potentiometer paralleling the feedback winding.

Earlier in the discussion it was mentioned that the time of response of a magnetic amplifier was affected by feedback. Since this characteristic largely determines their application, let us discuss this aspect further. The ordinary saturable reactor type, or saturable transformer, requires a certain time for a control action to take effect since the action is applied to an LR control circuit. The time of response is usually proportional to the time constant of

the d-c input control circuit. The time constant for this inductive circuit may be determined by the equation

$$t = \frac{L}{R}$$

where

t is in seconds.
L is inductance in henrys of the control winding.
R is the resistance in ohms of the control winding.

This time constant may be reduced by increasing the control circuit resistance, but this causes a control power loss. Degenerative feedback can be employed to do the same if the reduced gain can be tolerated. A normal arrangement would be to apply degenerative feedback and add more stages in cascade. When stages are cascaded, a d-c output of the first stage is applied to the control winding of the next stage, and so on.

SELF-SATURATING MAGNETIC AMPLIFIER

In order to understand the workings of magnetic amplifiers in general, a brief review of magnetics is in order. More specifically, the discussion at this time will deal with the special magnetic properties that are peculiar to magnetic amplifiers. These properties are generally referred to as "nonlinear magnetics."

NONLINEAR MAGNETICS

This category covers such subjects as voltage to time relations and voltage to flux relations. The first case is the much used volt-second concept and is of primary importance in an analysis of magnetic amplifiers.

From the continuity standpoint, the next logical step is to apply the above acquired knowledge to analysis of the operation of the basic magnetic amplifier. As will be explained shortly, the basic amplifier to be studied is of the self-saturating type. These devices are relatively new to industry in this country, and as the field has expanded, it has become evident that the self-saturating magnetic amplifier is increasingly dominating the field.

Domain

For the purposes of this course, the domain is considered as being an area within a ferromagnetic material, where the spin magnetic moments are alined in such a manner that the area itself is magnetized to saturation, giving a resultant field to the area.

Crystal Structure

A crystal is simply an orderly arrangement of atoms, sometimes referred to as a lattice. The pattern repeats itself regularly, as shown in figure 9-12.

This particular diagram shows only three cubic crystals. A ferromagnetic core will normally contain millions of these crystals and is called a polycrystalline substance. Each crystal itself may be composed of a great many domains and each domain may contain many atoms. This is not meant to infer that a crystal must always have many domains; a crystal may contain only one domain, and as conditions change, a domain can contain a great many crystals.

The single crystal has some important qualities that may be explored at this time. The first of these is the arrangement of the domains within the crystal. Figure 9-13 shows four possible arrangements. It must be realized that there are many possible arrangements and they are generally much more complex than those shown.

Figure 9-12. —Crystal structure.

864

Figure 9-13.—Possible domain configuration.

A study of these cases will reveal the fact that in all cases but one, the resultant field of the crystal is zero. This one exception occurs when the crystal contains only one domain.

Figure 9-14 (A) shows the Miller indices of a unit crystal. Because a crystal is easier to magnetize in some directions than others, it was found that a system of indexing was needed. This resulted in the Miller indices. As shown, each index lies in a plane with one of the dimensions of the crystal. The (100) index lies along the cube edge. The (110) index lies in a line that runs from corner to corner across the cube face, and the (111) index goes from corner to corner through the center of the cube. It has been found that an iron crystal will magnetize in the (100) plane with less energy applied than in either of the other two planes. The (110) plane is the next easiest direction of magnetization and the (111) the hardest. This is graphically shown in figure 9-14 (B).

Figure 9-14.—Magnetization in an iron specimen. (A) Miller indices; (B) ease of magnetization.

Magnetization

The core materials used in magnetic amplifiers are usually magnetized by a process called grain orientation (sometimes referred to as domain orientation).

GRAIN ORIENTATION.—Grain orientation is accomplished during the rolling and drawing process in the manufacture of tapes that are later wound into cores, similar to a roll of movie film on a bobbin. During this rolling and drawing process, the material is heated to a temperature above the Curie point and rolled thin through steel rollers. Throughout the rolling process, the material is under the influence of a strong magnetic field and the temperature is gradually lowered through the Curie point. This alines each grain or crystal so that its (100) index is alined with the applied field. When the tapes are wound on bobbins, the grains are alined with the direction that the externally applied field will follow.

APPLICATION OF AN EXTERNAL FIELD.—Because the domains are arranged in some fashion similar to those shown in figure 9-13, the resultant magnetization of the material before application of an external magnetic field is zero. Application of an external field has the effect of applying pressure to the domains in such a way as to cause them to try to aline themselves with the field. Those that are displaced from this field by 90° will be the first to switch, as the force is the greatest on them. As they switch, they unbalance those domains that are displaced by 180°, and they also switch. This action is called domain growth. Figure 9-15 shows this domain growth and the resultant level of flux within the core.

Notice that growth of the domains is in the direction of easy magnetization (100) and the domains originally alined in this direction grow at the expense of those not so alined. At the upper knee of the curve, all the domains have switched and the individual crystals are saturated. As the domain grows and saturates the crystal, each crystal will contain only one domain. It would appear that no more domain growth could occur from this point on, but this is not the case. A further increase in applied field will cause the individual domains to rotate on their axes and as some of these come into alinement, they will merge and become one larger domain.

Actually, domain switching and domain rotation overlap and a clearly definable point on the curve where one stops and the other starts is not possible. An important point to be made at this time is that the switching process is nonreversible but the process of domain rotation is a reversible action. This means that if the magnetizing force is removed, the domains will not switch back to their original state, but will rotate back to the state they were in before rotation. The above phenomena account for the relationship of saturation flux density (B_S) and residual magnetism (B_r).

Figure 9-15.—Domain growth.

Assume that the core has been left in its negative remanent state ($-B_r$). The polarity of the field then, by definition, is negative. If a very small positive external field is applied, no flux change will occur. As H is increased, there will be a point where domain switching begins. This value is commonly referred to as coercive force or "H_c". Imperfections on the surface cause the formation of "nucleation" points and switching starts at these points.

This switching changes the core state from negative saturation to positive saturation with a very minute addition of H beyond H_c. If the ratio of domain rotation to domain switching is small, the B-H loop will have very square corners. Applying the above theory to transformer cores in general, it can easily be shown that the nonoriented materials used in linear transformers would yield a B-H loop with less slope and rounder corners.

B-H LOOP TERMINOLOGY.—Figure 9-16 shows a typical B-H loop with symbols designating significant portions of the loop. The meanings of these symbols are listed as follows:

B_S is saturation flux density.

B_r is residual magnetism (remanence).

B_m is the maximum flux swing between $+B_S$ and $-B_S$; it is equal in magnitude to $2B_S$.

AT_1, AT_2, and AT_c designate loop width.

Volt-Second Concept

A clear understanding of the relationship between flux and voltage across a transformer can best be achieved through a study of Faraday's law. This law states that the rate of change of flux with respect to time is directly proportional to the amplitude of the applied voltage. From this relationship, it can be shown mathematically that the AMOUNT of change of flux density (rather than the rate of change) is directly proportional to the product of voltage multiplied by time. This is the volt-second concept.

Figure 9-16. —B-H loop terminology.

In the simplified situation just discussed, it is assumed that there is no limitation on the amount of flux change which might occur. That is, the core is not saturable. This is the situation shown in figure 9-17. Notice that the output is directly proportional to the input; each change of voltage in the primary winding (E_p) is duplicated by a change of voltage in the secondary winding (E_s). The core flux level (core ϕ) fluctuates but does not stabilize because the core is not saturable.

Figure 9-18 shows a saturable transformer and waveforms. In this arrangement, the same linear relationship exists between input and output as in figure 9-17, until saturation occurs (time T_2). After saturation, the relationship becomes very nonlinear, with positive excursions of E_p having no effect on E_s during saturation of the core. When E_p goes negative, the core becomes unsaturated and E_s is affected by both negative and positive changes in E_p. When the core reaches positive saturation again (time T_3) it holds E_s at zero again, as long as the E_p excursions remain above zero.

If a sine wave of voltage is applied to the input of the saturable transformer of figure 9-18, the waveforms will be as shown in figure 9-19. The assumptions are that the input is sufficient in amplitude to saturate the core at $+B_s$ and the core was set at an initial value of $-B_s$. Notice that $E_p = E_s$.

Either winding can support only so much voltage before core saturation occurs. When the core saturates, the impedance of the windings decreases to some low value and the device can no longer support the voltage on either winding. Also of primary interest is the area of the waveforms. Notice that the area of the output is the same as the area of the input. If the input is increased in amplitude, as shown to the right of the vertical dotted line, the core will saturate sooner and the output will also be higher in amplitude but of shorter time duration. If the input is reduced in amplitude, it will take longer for the core to saturate and

Figure 9-17. —Transformer and waveforms.

857 8388

Figure 9-18. —Saturable transformer and waveforms.

consequently the output will be of longer duration, but of lower amplitude.

The important thing to realize here is that in all three conditions, the areas of the waveform remained constant. Now, if the d-c average of the output were measured, it would be found that the d-c component of the output remains constant; for the average output of a waveform is a function of the ratio of areas of the waveform. This is a very important point

Figure 9-19. —Sine wave applied to saturable transformer.

in respect to all magnetic amplifiers and will hold true as long as the core saturates for some portion of the cycle of operation.

The volt-second-area (VSA) relationship may be more easily understood if one assumes an applied square wave, rather than the sine wave in the preceding case. Refer to figure 9-20 for the analysis. From time T_0 to T_1, a square wave of amplitude e_1 is applied to the primary of a saturating transformer. The rate of change of flux is shown directly below. The resultant secondary voltage is seen at the bottom of the figure.

If the amplitude of the pulse applied to the primary is decreased, the rate of change of flux will decrease accordingly, as is shown in the second condition (T_2 to T_3). As a consequence, the support voltage (e_2) will be of a greater time duration. From the relative amplitudes and time bases, one can more easily detect the constant supported VSA with changes in amplitude of the applied voltage.

Figure 9-20.—Application or square wave.

THEORY OF OPERATION OF THE SELF-SATURATING MAGNETIC AMPLIFIER

The basic self-saturating magnetic amplifier is shown in figure 9-21. The symbols used in the figure are as follows:

E_c—Control voltage (d. c.).
i_c—Control current.
R_c—Control circuit resistor.
N_c—Control winding.
N_g—Gate winding.
E_g—Gate voltage (developed across N_g).
E_a—Applied signal voltage.
R_L—Load resistor.
E_o—Output voltage.

Condition I in figure 9-21 (zero control current) yields a maximum output. This is because the rectifier allows current to flow in only one direction through the gate windings. If the first pulse drives the core into positive saturation, then there will be no back voltage on the following half-cycle (due to rectifier action) to reduce the core flux. If the core flux cannot change, the winding can support no voltage, hence E_o is maximum.

If d-c control current is now added in such a direction as to reduce the core flux while gate current is being blocked, then the flux must change back to positive saturation on the following half-cycle. This is shown in II. Notice that the core flux waveform is shown at a reduced level slightly ahead of the start of cycle II. This change in flux allows the gate winding to support voltage until the core is again saturated. Because N_g and R_L are in series, the voltage seen across N_g must subtract from E_o.

As control current is increased (III), the reset flux increases and the gate can support a progressively longer pulse. Therefore, the output decreases accordingly until finally (IV), the windings are able to support the full supply and E_o drops to its minimum value. Thus, by the use of a d-c control current, it is possible to control the average output current.

Excitation Voltage

Excitation is the result of applying the supply voltage to the circuit. There are three conditions of excitation: namely, exactly excited, overexcited, and underexcited. Each of these conditions is utilized to some extent in the circuitry.

Figure 9-21. —Effects of control.

First, consider the condition of exact excitation or normal excitation. If the supply voltage is of such a magnitude as to cause the core flux to swing just below the value of B_m ($2B_s$), the device is operating with normal excitation. To determine the amount of supply voltage to use with a given number of gate windings, Faraday's law can be used. If the supply voltage is known, the gate turns may be determined by manipulating the mathematical formula which expresses Faraday's law. By transposing the formula, an increase in voltage or decrease in turns gives a condition of overexcitation. Reversing the changes gives a condition of underexcitation.

The three conditions of excitation can be shown on the control characteristics curve. Refer to figure 9-22.

Figure 9-22. —Effect of excitation voltage.

Hysteresis Effect

Up to this point, in order to simplify the introduction to magnetic amplifiers, the effect

of hysteresis has been neglected. In order to fully understand the operating characteristics of magnetic amplifiers, it is important to know how these characteristics are affected by the shape of the hysteresis loop.

The curve in figure 9-23 (A) represents a typical rectangular shaped B-H curve; the curves in (B), (C), and (D) show the operation for various amounts of control action.

Further use of the circuit in figure 9-21 is made in explaining the effects of hysteresis. This circuit actually has two distinct periods of operation. The period during which the rectifier conducts is known as the "operating period"; the other half-cycle of the alternating current is known as the "control period."

In the explanation of the effect of the hysteresis loop of figure 9-23 (A), assume that control current is zero and that the load winding current is of such amplitude that it will saturate the core during peak conduction. During the first operating period, conduction through the load winding will cause the core flux to build up along the dotted line from the point of origin, o, to the point of saturation, a. At the end of this period, the flux level in the coil returns to point b rather than to zero because of the retentivity of the core. This is called the remanence point in magnetics and leaves the core in a magnetic state, similar to a permanent magnet. Thus, with no control current the core flux will remain at point b and during each positive half-cycle the core will saturate immediately. Under this condition the load current will be maximum, for no control is exercised.

Figure 9-23 (B) shows the action when a small control current is added. The operation during the first half-cycle is similar to that just described in connection with figure 9-23 (A), but during the second half-cycle (control period), the flux will reset from point b to point c. This occurs because the direction of the control flux in the core is opposite to that of the operating flux.

This positioning of the residual flux is called "resetting." During the next half-cycle the flux starts increasing from point c in the figure and a small period of this half-cycle is used before the flux reaches saturation at point a. At this point the core is saturated and the rectifier is in maximum conduction for the remaining part of this half-cycle. At the end of the operating period the flux returns to point b where the control period starts and resets to point c where the cycle starts repeating itself. The output for this condition is shown as the shaded portion of the waveform of figure 9-23

Figure 9-23. —Operation of a magnetic amplifier showing effects of hysteresis.

871

(B). Figure 9-23 (C) and (D) shows the operation for increasing amounts of control action. The operation in each case is basically the same as for figure 9-23 (B).

It may be seen that the action described in the analysis mentioned above in similar to that of a thyratron. The control signal sets the point of amplitude at which the source voltage causes saturation of the core and reduces the impedance in series with the load winding to a very low value. In the thyratron, the control signal on the grid sets the point of amplitude at which the source voltage causes the tube to ionize, which results in a decreased impedance. The term firing, as it relates to the thyratron, is frequency used in connection with magnetic amplifiers interchangeably with the term saturation.

PERFORMANCE CHARACTERISTICS

This discussion of magnetic amplifiers has been limited, up to this point, to the mechanics of operation of the self-saturating magnetic amplifier. No mention has been made regarding such parameters as gain, bandwidth, etc. These topics are discussed in the following paragraphs.

Gain

Most manufacturers of magnetic amplifiers list the gains of their devices as being a ratio of the output voltage to the control current. This ratio is called the transresistance of the amplifier and is formulated as $A = E_o/i_c$. This ratio may easily be transformed into either voltage, current, or power gain, if the input and/or output resistances are known.

In order to obtain a better insight into the factors that affect the amplifier gain, the basic formula for transresistance will be built upon with the aid of Faraday's law. The simplified statement of Faraday's law given earlier in this chapter does not include N, the number of turns in the windings. The full expression of the law reduces mathematically to

$$e = \frac{N\phi}{t} \times 10^{-8}$$

It t represents the period of the output voltage E_o, then 1/t is the frequency of the signal being amplified. Therefore,

$$E_o = N\phi\ f \times 10^{-8}$$

This expression shows that the voltage gain (E_o) during one cycle is directly proportional to the number of turns (N), the flux (ϕ), and the frequency.

The number of parameters which affect the gain will be easier to see by analyzing the quantity ϕ. It can be shown mathematically that

$$\phi = \frac{4\pi\mu\ N_c N_g i_c A_c}{L_c}$$

where

μ = B/H.

N_c = Number of turns in control winding.

N_g = Number of turns in gate winding.

i_c = Control current.

A_c = Cross sectional area of the core in centimeters.

L_c = Length of the core in centimeters.

Therefore

$$E_o = \frac{4\pi\mu\ N_c N_g i_c A_c f}{L_c} \times 10^{-8}$$

The expression

$A = E_o/i_c$ then becomes

$$A = \frac{4\pi\mu\ N_c N_g A_c f}{L_c} \times 10^{-8}$$

Bandwidth Considerations

Another important parameter in the design of any amplifier is the bandwidth of the amplifier, exclusive of the interstage circuitry. Bandwidth is usually given in cycles per second and is determined by the point at which the output drops 3 db below midfrequency value. This drop in gain is a result of varying the frequency of the input signal and may occur at both the low and high ends of the frequency spectrum. However, the magnetic amplifier is capable of responding to a d-c signal without any attenuation of the output. Therefore,

the bandwidth of the magnetic amplifier will be determined by the upper frequency point.

Because the control circuit is basically an L/R circuit, it will be these values that will determine the bandwidth of the amplifier. However, this is not a simple first order time constant circuit, as the output voltage fluctuations will in most cases affect the input inductance. Therefore, the values of resistance and inductance that will be used are the EFFECTIVE values.

For any time constant circuit, the cutoff frequency (f_c) may be determined by the formula:

$$f_c = \frac{1}{2\pi T_c},$$

where T_c is the time constant. The control circuit time constant of the magnetic amplifier is determined by the above formula, where T_c is the ratio of the effective inductance of the control circuit to the effective resistance of the control circuit. The resistance is referred to as "effective" because the effective control loop resistance may be changed, without changing the actual resistance of the loop. This is one of the effects of feedback.

Feedback

To discuss the effects of feedback, first consider the action of the amplifier with a total lack of feedback. In comparing the action of the saturable reactor with the basic half-wave self-saturating magnetic amplifier, we need only remove the diode from the circuit of the self-saturating amplifier and we have the basic saturable reactor. We will make this comparison because the self-saturating amplifier has an inherent feedback that is exactly analogous to adding feedback to the basic saturable reactor.

To understand why this is referred to as feedback, consider the action of the control current. We know, from the mechanics of operation, that the control current resets the core flux during the time that the diode is blocking the supply current in the gate circuit. Therefore, the control current does not have to oppose the gate current to reset the flux level to some value on the control half-cycle. If we remove the diode from the gate circuit, the control current must oppose the action of the gate current in order to reset the core flux. Consequently, more control current is needed to achieve the same effect as with the diode present. This means that there must be more control current to accomplish the same gate voltage excursion, and when relating this to gain, one can see that the amplifier without the diode would have the lower gain.

External feedback, as applied to magnetic amplifiers, may be divided into two basic categories, these being magnetic and electric. These types may be used individually or in combination, depending on the results desired, and also that distinctly different effects can be had from each type. Further, in most cases, the magnetic feedback is a built-in feature of the amplifier, whereas the electric feedback may be applied to any amplifier.

MAGNETIC FEEDBACK.—Magnetic feedback is accomplished by feeding back a portion or all of the output current in such a fashion as to directly affect the core flux. This is not, however, referred to as current feedback. Magnetic feedback is achieved by forcing feedback current through a tertiary winding placed on the core. If the output of the amplifier is d.c., then this current may be fed to the feedback winding directly without the need of rectification. If, however, the output of the amplifier is a.c., then the current must first be rectified, and then applied to the feedback winding. The feedback current will then be a direct current, proportional to the load current. This current may be applied in such a fashion that it is either regenerative or degenerative, depending on the action of the generated flux in respect to the circuit action. Figure 9-24 shows the basic doubler circuit with external magnetic feedback applied.

The amount of feedback is a function of the relation between the flux generated by the gate winding and that generated by the feedback winding. This ratio is a function of the ampere-turns ratio of the feedback circuit to gate circuit. The ampere-turns of the feedback circuit may be controlled by external means, either by controlling the current flowing through the winding or by adjusting the number of turns, as with an adjustable tap.

Magnetic feedback is considered to be external feedback, where the self-saturating magnetic amplifier is considered as employing a comparable inherent feedback. It should be realized at this point that both internal and external feedback may be applied to the same

Figure 9-24. —Full-wave doubler with external magnetic feedback.

amplifier. As was previously mentioned, magnetic feedback is one of the basic types of feed back, the other type being electric. It is not uncommon to encounter an amplifier employing both internal, magnetic, and electric feedback.

ELECTRIC FEEDBACK. —This type of feedback may be further divided into two classes, these being voltage and current. Both types are accomplished by forcing all or a portion of the output to flow in the control circuit in such a manner as to influence the signal applied to the control winding. The feedback circuitry is completely external to the amplifier proper; as a consequence, it does not affect the gain of the amplifier proper, but does affect the stage gain.

The characteristics of the voltage feedback circuit are as follows:

1. Output appears as a constant voltage source.
2. Output voltage is insensitive to load fluctuations.
3. Output voltage remains relatively constant.
4. Output appears as a low impedance source.

Current feedback has the following characteristics:

1. Output appears as a constant current source.
2. Output current is insensitive to load fluctuations.
3. Output current remains relatively constant.
4. Output appears as a high impedance source.

The feedback circuit in figure 9-25 consists of the voltage divider network composed of R2 and R1. Notice that these resistors are in parallel with R_L, and the voltage seen across R_L will also be felt across R2 and R1. The voltage across R1 will also be present in the control loop, composed of the signal source (E_S), the source resistance (R_S), the control winding resistance, and R1. The signal voltage will be divided across R_S, the control winding resistance, and R1, all in series. The current that will flow in the control winding will be a result of the algebraic sum of the voltage drops around the loop. Because of the polarities involved, the voltage dropped across R1 will oppose the signal voltage; hence, the feedback is degenerative. This is most generally the case when electric feedback is employed.

Figure 9-26 shows the basic current feedback circuit. Note that the load current flows through the resistance R1 in such a fashion as to oppose the input signal. Again, the feedback is degenerative. The amount of feedback in this case is a function of the value of the feedback resistance, R1. The improvements realized by the application of current feedback are

Figure 9-25. —Voltage feedback.

874

Figure 9-26. —Current feedback.

comparable to those realized by using voltage feedback, and the characteristics are those listed in the first portion of the analysis of electric feedback.

In summation, the basic amplifier employing no feedback is seldom encountered in the modern circuitry. The amplifiers in use today will almost invariably employ some form of feedback. The type used will be determined by the application of the amplifier.

APPLICATIONS OF MAGNETIC AMPLIFIERS

The magnetic amplifier has found application in almost all circuits which use vacuum tubes and many which do not. They may be found in such circuits as audio amplifiers, voltage regulators, servoamplifiers, computer counting and dividing circuits, and many high frequency circuits. However, the Aviation Electronics Technician will be mainly concerned with their application in servosystems and in the various operations of computers.

ELECTRONIC POWER SUPPLY REGULATOR

Many aviation electronic equipments contain voltage regulated power supplies. The accuracy of the voltage produced by these supplies is important insofar as proper operation and maximum life of the equipment are concerned. Present day electronic equipments contain many timing, waveshaping, and other critical circuits that require a constant d-c voltage source.

Figure 9-27 (A) shows a power supply which used a magnetic amplifier to regulate the d-c output voltage. In this circuit the conventional filter choke has been replaced by a saturable reactor, T2. The voltage regulator (VR) tube (V1) produces a constant reference voltage across coil B and acts as a current amplifier for the control winding, A. Coils A and B control the saturation of T2, hence the inductance of the load winding. This action effectively transfers filter capacitor C to

Figure 9-27. —Power supply using magnetic amplifier voltage regulator.

875

the other side of the choke when the core is saturated. The end result is that the power supply alternates between a choke input and a capacitor input type of supply; thus a constant voltage output is produced.

Figure 9-27 (B) shows a variation of figure 9-27 (A) in which saturable reactor T2 is connected in series with the primary of power transformer T1. An advantage of this circuit arrangement is that a regulated filament voltage is also produced.

The significance of constant filament voltage is appreciated when it is realized that the incidence of failure rises rapidly when the cathode or filament temperature exceeds optimum. This does not include transformer, choke, and resistance failures which can usually be traced to overloads occurring during these failures.

SERVOSYSTEMS

One of the most common used of magnetic amplifiers in aviation today is in connection with servosystems. Figure 9-28 illustrates the use of a magnetic amplifier as the output stage of a servoamplifier. The function of the servoamplifier is to amplify the servo error signal sufficiently to drive the servomotor. For a review of servosystems, refer to chapter 19 of Basic Electricity, NavPers 10086-A.

Before discussing the magnetic amplifier, let us briefly review the operation of an a-c servomotor. The output of the servoamplifier

Figure 9-28. —Magnetic amplifier used as an output stage of a servoamplifier.

is connected to one of the motor windings (controlled winding W1) while the other winding (uncontrolled winding W2) is connected across the a-c source in series with a capacitor. The capacitor provides the required 90° phase shift necessary to cause motor rotation. The phase relationship of the current through the two windings determines the direction of rotation of the servomotor.

The input to the amplifier shown in figure 9-28 is a d-c error signal and is applied to the grid of V1. Tube V1 and V2 constitute a cathode-coupled paraphase amplifier working into two saturable reactors (magnetic amplifiers). The secondaries of the two saturable reactors and the two halves of the secondary of T3 form an a-c bridge circuit. The motor winding (W1) is connected across the bridge as shown. With a zero error signal applied, both tubes draw equal amounts of plate current partially saturating T1 and T2. Since the degree of saturation of the two saturable reactors is equal, the bridge circuit is still balanced and no current will flow in W1.

When a positive error signal is applied, V1 will conduct heavily while V2 will be near cutoff. At this time the secondary inductance of T1 will be practically zero. Motor winding W1 will be effectively connected across points a and b of T3 and supplied with an a-c source. Also at this time the secondary inductance of T2 will be very large (effectively an open circuit).

In a similar manner, when V2 conducts heavily, V1 will be near cutoff, the secondary inductance of T2 will be near zero, and the secondary inductance of T1 will approach maximum. Under these conditions, motor winding W1 is now effectively connected between points b and c of T3 and is supplied an a-c voltage that is 180° out of phase with the previous condition.

877

CHAPTER 10

AIRCRAFT COMPUTER APPLICATIONS

Automatic computers are becoming increasingly common as a part of the electronic installations in naval aircraft. Present and future technicians will be faced with a collection of electronic equipments which use computers as integral portions of the overall system. To understand the operation of the system in general, and the computer portion in particular it is necessary to have a basic understanding of computer functions, circuitry, terminology, and applications. Basic Electronics, NavPers 10087-B, chapter 16, presents a basic coverage of the purpose, operation, and theory of computers, together with some of the terminology peculiar to them. In addition, chapters 14 and 15 of Aviation Electronics Technician 3 & 2, NavPers 10317-C, present coverage of some of the basic circuits of computers. Review and study of these basic coverages will aid in understanding the material covered in this chapter.

REVIEW OF COMPUTER PRINCIPLES

A COMPUTER is any device capable of accepting information, applying mathematical operations to that information, and obtaining the results of these operations. From this definition, it is obvious that any computer must have three fundamental components—input, processing, and output.

Computers in use today are performing many functions, among which are the following:

1. Solving design problems of many different types.
2. Solving problems in personnel, fiscal, and stock control management.
3. Processing information from missile ranges and tracking stations.
4. Automating processes.
5. Training by simulation.
6. Forming a part of complex military systems and operations on land, at sea, and in the air.

As a part of naval aircraft systems, computers are used in connection with AEW, ECM, ASW attack, reconnaissance, intercept, and command missions. They perform such functions as communications link and relay, navigation, fire control, tracking, strategy, tactics, logistics, selection and identification of targets, etc. It is obvious that computers, with such wide and diverse usage, will form a considerable part of the technical responsibility of the AT as well as personnel from other ratings.

Basically, computers are divided into ANALOG and DIGITAL types, but many actual equipments are combinations of the two. The combination is called a HYBRID computer. The basic difference between the analog and the digital computer is not in the type of problem solved, but in the manner of representing the quantities involved in the solution. Analog quantities are usually represented by magnitude or angular displacement signals; digital quantities are usually represented by encoded "binary words."

A SPECIAL PURPOSE computer is one designed for a specific type calculation, such as navigation. A simple computer may be able to calculate ground track (ground velocity and direction). By proper selection and interconnection of units, it is possible to have a computer that will indicate the present position of an aircraft, course and distance to a preselected target, course and distance to home, estimated time of arrival at either or both, and whether sufficient fuel is available for the flight. As the problems become more and more complicated, so does the overall equipment. However, even the most complex equipment is made up of many relatively simple components.

By increasing the number of computing units and making the interconnection of these units sufficiently flexible, the computer may be used to perform almost any type computation. A computer of this type is called a GENERAL PURPOSE computer. There are very few

878 878

general purpose analog computers, most general purpose computers being digital. Because of the necessary complexity, general purpose computers are too large and heavy for airborne use; their use is normally limited to shore-based activities, or to the larger ships. Nearly all airborne computers are of the special purpose type.

To be of any practical value, the computer must be properly organized. Proper organization of a computer requires the following characteristics:

1. The computer must be supplied with the information upon which its computations are to be based. This is called the INPUT.

2. The inputs must be applied in the proper manner, to the proper circuit element, at the proper time, and in the proper sequence. This requirement holds true for each step in the overall solution process.

3. Each circuit must be capable of perforing the steps required of it, within the required degree of accuracy. It must also be properly interconnected to deliver its partial solution to the circuit which is to perform the next step of the problem.

4. A conversion unit must be provided to change the data measured or calculated into a form usable by the computing circuit, and the scale factor of this conversion must be one which the computer can use.

5. Some method must be provided for checking the accuracy of calculations. In addition, some means of adjustment must be included to compensate for changes in the operation of the equipment to manintain this accuracy.

NOTE: Items 2 through 5 of this listing are frequently grouped and referred to as the PROCESSING function.

6. The overall result of computer operation (the answer) must be presented in a manner that is useful to the operator. This is called the READOUT of the computer.

DIGITAL COMPUTER PRINCIPLES

Digital computers are finding increasingly wide application in Navy aircraft. Some aircraft now operational, and others that will become operational in the near future, have computers installed as integral parts of the electronics system. Among the more common applications in Navy aircraft at present are the navigation weapons delivery systems, tactical communications systems, ASW and ECM systems, and automatic flight systems.

The ability to make calculations is built into the computer by proper combinations of relatively simple circuits. A computer also has the ability to retain information by storing it in memory banks. This information, fed to the computer by an operator, is available whenever the operator calls for it. In most airborne computers, information is stored in the form of magnetic charges, and is stored for varying periods of time—from a few milliseconds to years—depending upon what use is to be made of it.

When a computer performs an operation, it does so by comparing quantities representing data that have been placed into it. Its output consists of data that must be "read" and automatically translated into some form of understandable language.

Since the airborne digital computer performs all of its functions by using coded numbers, it follows that any information to be fed to the machine must be transposed from plain language into the proper coded number form.

The type of coding normally used in digital computers is based on the binary number system, as explained in chapter 16 of Basic Electronics, NavPers 10087-B. Chapter 2 of Mathematics, Vol. 3, NavPers 10073, also contains information on the binary system as well as other number systems which are of interest to the AT in a study of digital computers.

MAJOR UNITS

Digital computers contain blocks of circuits and machinery that can be broadly broken down into the input-output unit, the memory unit, the arithmetic unit, and the control unit. (See fig. 10-1.)

Figure 10-1.—Fundamental units of a digital computer.

Input-Output

The input-output unit is just what the name implies; that is, it is the unit into which information is fed, and from which information is taken out. Information may be supplied to a computer by any of several means, a few of which are as follows:

1. Punched cards (most Navy paychecks have perforations which, when fed into a computer, identify the check with the issuing activity and with the person to whom the check was issued).
2. Magnetic tape (similar to the tape used in common tape recorders).
3. Received pulses of radio transmission.
4. Modified or converted data read from aircraft or other instruments.
5. Telephone line or keyboard.

All of these and many others may be fed individually (or in combinations) to a computer which is built to accept that type input. They all do the same thing—feed pertinent data to the computer so that a logical solution to the problem may be obtained.

The output unit translates the result of the computer's operations into a visual indication, or into some other form that is readily usable. The output of a computer may operate a relay or a light, or it may be used to position some mechanical device (such as a pointer, a rudder, or a dial). In large computers, the output may operate an electric typewriter.

Memory

The memory unit stores information until it is needed. Data fed to the computer will be directed to the memory unit. Such data includes INFORMATION and INSTRUCTIONS. Instructions tell the computer what operations to perform, the order in which to perform them, and what to do with the results. Information deals mainly with the quantities involved in the calculations. Data may be fed into the computer in either serial or parallel form. In serial form, the individual instruction and information bits are fed in the sequence in which they are to be used, one bit at a time. This is a comparatively slow process, but may be accomplished with relatively simple circuitry. Parallel input permits two or more information and instruction bits to be fed into the computer at the same time, resulting in a much faster rate. More complex circuitry is required for parallel inputs. In a practical computer, instructions and information may be fed into the computer at the rate of 3 million bits per second, using the parallel input. With serial feed, rates as high as 50,000 bits per second are common.

Arithmetic Unit

The arithmetic unit is the calculating unit. It contains circuits that are simple in both theory and operation. It performs mathematical operations—addition, subtraction, multiplication, and division—by performing logical operations. It must be remembered that all mathematical calculations dealing with numbers take some form of one or more of these basic operations. For instance, squaring a number is merely a special form of multiplication; extracting a square root involves all four operations in a special order. Similarly, an exponential curve is simply the result of many instantaneous values computed by arithmetic means.

By comparing data quantities against each other, the arithmetic unit is able to make logical decisions. For example, it is able to determine the proper bomb release point by considering aircraft speed, windspeed and direction, drift, ballistics information regarding the particular bomb, altitude, and other factors that have been fed to it, and then to provide a "yes or no" answer to specific questions. The solution to a given problem is sent from the arithmetic unit to the memory unit where it remains in storage until needed for further calculations, or until otherwise routed by the control unit.

Control

The control unit of a computer ties all parts of the computer together, causing them to function as an integrated system. Its functions are the same as for the control unit of any system, in that it maintains complete control over every operation the computer performs.

Computer Logic

Digital computers are used to make logical decisions (but not to reason) about matters which can be logically decided. Some logical decisions that a computer may be required to make are when to perform an operation, what operation to perform, and how (of several ways) to perform it. Keep in mind that digital computers

880

never reason why or think out an answer. They operate only on instructions prepared by a man who has applied the thought process to a problem and has reduced the problem to a point where logical decisions can deliver the correct answer. The rules for the equations and manipulations employed by the computer differ in many cases from the familiar rules and procedures of everyday mathematics. For this reason, the AT should have an understanding of the basic concepts involved in computer logic.

Many logical truths are used by people in everyday life without their realizing it. Most of the simple logical patterns are distinguished by words such as AND, OR, NOT, if, else, and then. Once a verbal reasoning process has been completed and the results put into statements, there are laws of logic which can be used to evaluate the process. Although simple logic operations can be performed by manipulating the verbal statements, the structure of more complex relationships can more usefully be represented by the use of symbols. Thus the operations are expressed by what is known as symbolic logic.

The symbolic logic operations utilized in digital computers are based on the investigations of George Boole, and the resulting algebraic system is called Boolean algebra. It is similar in some aspects to the algebra with which the AT is familiar; however, it follows different laws and rules.

Truth Tables

A truth table is a chart used in connection with logical circuits to illustrate the states of the inputs and outputs of a given stage under all possible signal conditions. It provides a ready reference for use in analyzing the operating theory of the circuit, and is useful in developing the overall signal flow diagram.

In devising the truth table, it is necessary to know the number of inputs and their polarity. All possible states of the input are listed in column form, with a separate column for each input line. Then the output for each of the possible input states is determined and noted in an output column. In logic circuits employing bistable devices, the number of possible input combinations in the truth table will be 2^n, where n = number of input lines.

For example, a truth table constructed for a conventional pentode coincidence amplifier would be as shown in table 10-1. The circuit constructed in such a manner that an output occurs only when an input is applied simultaneously to the control grid and suppressor grid.

In constructing table 10-1, all possible input combinations were placed in column form, and the output for each combination was determined and noted. In this particular example, the number of possible inputs also follows the rule for bistable devices; that is, with two inputs the table contains 2^2 or 4 combinations.

In computer logic circuit truth tables the column headings will normally contain letter designation for the input and output. Also, the "Yes and No" will be replaced by symbols to denote the state of the inputs and outputs. The symbols which the AT will encounter include binary 1's and 0's, plus and minus signs, or H and L (High and Low). Using symbols to construct the truth table for the coincidence amplifier, it would appear as in table 10-2.

The meanings of the symbols in table 10-2 are as follows:

A = Control grid input.
B = Suppressor grid input.
Z = Output signal.
1 = Signal present.
0 = No signal present.

Some truth tables will be presented later in this chapter in the discussion of Boolean algebra and logic circuits. The truth table shown in the previous example is actually the truth table for a two-input AND gate. The coincidence amplifier is one of the standard electronic circuits which can also be used as a logic circuit.

Table 10-1. —Coincidence amplifier truth table.

Control grid input present	Suppressor grid input present	Output signal present
NO	NO	NO
NO	YES	NO
YES	NO	NO
YES	YES	YES

Table 10-2—Truth table symbols for coincidence amplifier.

A	B	Z
0	0	0
0	1	0
1	0	0
1	1	1

When plotting a truth table for a circuit involving a large number of inputs, a convenient method of getting all possible inputs listed is to start with all zeros and then count in binary sequence until the correct number of combinations has been listed. The last binary number listed in the input side of the table will be one less than the number of required inputs. Note in table 10-2 that there are 4 input combinations, and the last input is 11 or binary 3.

Boolean Algebra

The objective of using Boolean algebra in digital computer study is to determine the "truth value" of the combination of two or more statements.

Due to the fact that Boolean algebra is based upon elements having two possible stable states, it becomes very useful in representing switching circuits. The reason for this is that a switching circuit can be in only one of two possible stable states at any given time; that is, the state of being open or the state of being closed. These two states may be represented as 0 and 1, respectively.

Since the binary number system consists of only the symbols 0 and 1, we employ these symbols with the Boolean algebra and it can be thought of as binary Boolean algebra.

In the mathematics with which the AT is normally concerned, there are four basic operations—addition, subtraction, multiplication, and division. In Boolean algebra there are three basic operations—AND, OR, and NOT. If these words do not sound mathematical, it is only because logic began with words, and not until much later was it translated into mathematical terms. The basic operations are represented in logical equations by the symbols in table 10-3.

The OR operation is indicated by the addition symbol, while the AND operation is indicated by the multiplication symbol. In addition to the dot, parentheses and other multiplication signs may be used. The negation function may also be indicated by A' instead of $\overline{A}$. Some examples of combinations of these symbols are given in table 10-4.

The basic logic operations and some combination logic operation will be presented in this section. In addition to the Boolean expression and an explanation for each operation, a truth table, equivalent switching circuit, and logic diagram symbol will be given.

THE "AND" OPERATION.—The truth table of an AND operation (fig. 10-2(A)) can be understood if one thinks of the logic involved. If either A or B (or both) take the condition of 0, then AB is equal to 0. When both A and B take the condition of 1, then AB is equal to 1.

The switch circuit in figure 10-2(B) is an equivalent circuit for the AND operation. Inspection of the switch arrangement shows that the resulting circuit will be completed only if both A and B are closed (that is, equal to 1). If either switch is open (equal to 0), the resulting circuit will not be completed. This allows us to define an AND circuit as follows: In an AND circuit the output is 1 only when all of the inputs are 1's.

In any digital computer equipment, there will be many of the circuits which perform the logical operations. In order to analyze the operating principles of a computer without extensive electronic circuit tracing, a group of logic diagram (block diagram) have been devised. The standard computer logic symbols are included in the appendix to this course which

Table 10-3.—Logic symbols.

Operations	Meaning

A + B′	A OR B NOT

lists electronic symbols. The logic diagram for the AND circuit is shown in figure 10-2 (C). This diagram means that there are two inputs, A and B, into an AND operation circuit producing the output in Boolean form of AB. Such diagrams simplify equipment circuits by indicating operations without drawing all the circuit details.

THE "OR" OPERATION. —The truth table for the OR operation is shown in figure 10-3 (A). This truth table bears out the following definition of an OR circuit: The output of an OR circuit will be a 1 when any one (or more) of the inputs is 1. Since the OR circuit reresents the logical concept of "one or more" and thus expresses inclusion, a more precise name for it is "INCLUSIVE OR." Although this name is seldom used, the distinction between inclusion and exclusion is made by giving the name EXCLUSIVE OR to the circuit which represents the logical concept of "one and only one." The EXCLUSIVE OR circuit is discussed later in this chapter.

The switching circuit (fig. 10-3(B)) shows that the circuit would be completed if either A or B were closed. The logic diagram for the OR circuit is shown in (C) of the figure. This diagram shows an output of A + B which is the Boolean expression for the output of an OR gate.

THE "NOT" OPERATION. —The NOT operation in logic is the negation function. Figure 10-4 (A) shows the truth table for the NOT function while the switching circuit and logic diagrams are shown in (B) and (C), respec-

Figure 10-2. —The AND operation.

tively. The requirements of a NOT circuit are as follows:

1. A signal injected at the input must produce the complement (opposite or inverted signal) at the output.

2. The presence of the complement of the signal at the input must produce the signal at the output.

In the switching circuit, when switch A is closed (equal to 1) the relay opens the circuit to the load and the output is the complement of the input or 0. When switch A is open (equal to 0), the relay completes the circuit and the output is the complement of the input or 1. The two logic diagrams employing

the standard inverter amplifier symbol depict both of the conditions of the truth table. The small circle on the triangle (amplifier block diagram symbol) indicates the low level side of the inversion circuit. The third symbol, the circle enclosing an I, is another symbol sometimes utilized to show the NOT (inversion) operation.

THE "NOR" OPERATION.—The truth table for the NOR operation is given in figure 10-5 (A). The table shows that if either A or B is 1 then the output $\overline{A + B}$ is 0. Furthermore, if both A and B are 0, the output is 1.

The NOR operation is a combination of the OR operation and the NOT operation. The

NOR switching circuit (fig. 10-5 (B)) is the OR circuit placed in series with the NOT circuit. If switch A, or switch B, or both are in the closed position (equal to 1), then the circuit is not completed. If switches A and B are both open (equal to 0), then the circuit is completed. The logic diagram for the NOR operation is shown in figure 10-5 (C); A +

Figure 10-6. —The NAND operation.

B is the output of the OR gate portion and $\overline{A + B}$ (A OR B negated) is the output of the complete operation. Note that the entire quantity is complemented and not the separate variables.

THE "NAND" OPERATION. —The NAND operation is a combination of the AND operation and the NOT operation. The truth table for this function is given in figure 10-6 (A). When A and B equal 1, then the output is 0. In all other cases the output is 1.

The switching circuit in (B) of the figure shows the AND circuit placed in series with the NOT circuit. If either switch A or B is open (equal to 0), the relay will not energize and the output circuit is completed. If both of the switches are closed (equal to 1), the relay energizes and the output circuit is opened.

Figure 10-6 (C) shows the diagram for the NAND operation. The logic diagrams for both the AND and the NOT operations are used to show the NAND operation. There are two inputs, A and B, into an AND gate producing an output of AB. This quantity is the input to the NOT circuit which gives an output, in Boolean form, of $\overline{AB}$. This is spoken as "AB

negated" or "A and B quantity notted." In the NAND operation, as in the NOR, it is important to note that the entire quantity is complemented and not the separate variables.

THE "INHIBIT" OPERATION.—A circuit which performs the INHIBIT operation is a combination of an AND circuit and a NOT circuit, with the NOT circuit placed in one input leg of the AND gate.

The truth table, switching circuit, and logic diagram symbols for the INHIBIT operation are depicted in figure 10-7 (A), (B), and (C), respectively. In this explanation the NOT function is placed in the B leg of the AND gate. In actual computer circuitry the NOT operation can be in any of the AND gate input legs.

Inspection of the truth table shows that the circuit's output is 1 only when A equals 1 and B equals 0. The switching circuit diagram indicates that the circuit is complete only with switch A closed and switch B (the inhibit input) open. An INHIBITOR circuit will have an output of 1 only when all of the regular input terminals have an input of 1 and the input at the inhibit terminal is zero.

The logic diagram symbols for the INHIBITOR show two inputs, one fed through an inverter, and an output Boolean expression of $A\bar{B}$ (A AND NOT B). Note that one variable is complemented and not the entire expression. The lower diagram, with the input to the inhibit terminal showing the inversion function by a small half-circle, is the most commonly used symbol for an INHIBITOR.

THE "EXCLUSIVE OR" OPERATION.—The EXCLUSIVE OR operation (fig. 10-8 (A)) differs from the OR operation shown in figure 10-3. In the OR operation, an output of 1 occurs when either or both inputs are 1's. The EXCLUSIVE OR circuit has an output if either one of the inputs is a 1, but not when both are 1's. Switch A or B could be closed to complete the circuit, but not both.

The logic diagram symbol for the EXCLUSIVE OR circuit is shown in figure 10-8 (B). The (C) and (D) portions of figure 10-8 show two of the possible logic circuit combinations which will produce the EXCLUSIVE OR operation; the figure also shows truth tables for these diagrams.

The (C) portion of the figure is a combination of an AND gate and an OR gate feeding an INHIBITOR, with the AND gate connected to the inhibit terminal. The circuit in (D) consists of two INHIBITORS feeding an OR gate. In one of the INHIBITORS, the A input is connected to the inhibit terminal; in the other, the B input is connected to the inhibit terminal. The Boolean expression for each of these circuits is shown on the figure. The truth tables show that the EXCLUSIVE OR circuits have an output if either one of the inputs is present, with no output if both are present.

Simplification of Boolean Expressions

The preceding section of this chapter introduced the logic operations and the Boolean expressions which describe the various operations. These operations, and the corresponding Boolean expressions, are relatively simple when taken individually. However, when computer circuitry is designed to include all of the functions required, the logic diagrams are very complex. Through the use of Boolean algebra, these complex circuits can be modified and simplified witnout changing the logic of the original circuit.

Some of the reasons for simplification of computer circuitry are as follows:

1. Reduce cost by reducing number of components.
2. Simplify the actual circuit operation.
3. Reduce percentage of breakdowns, and consequently reduce time and money spent for repairs.
4. Economize by reducing power consumption.

887

The actual process of simplification of computer circuitry is a design process. However, the AT should have a knowledge of Boolean algebra and the simplification process as a foundation for understanding digital computer theory. This foundation of basic knowledge will be essential for an understanding of any advanced texts on digital computers.

BASIC LAWS. —In the simplification of Boolean expressions, there are certain laws which must be followed, just as there are laws and postulates in ordinary algebra. The laws of Boolean algebra are listed in table 10-5. Any changes in Boolean expressions based on the listed fundamental identities represents a physical change in the electrical network without a change in relationship between input and output signals. Boolean algebra provides a means for making changes in a logical diagram in the search for a more desirable network for a given expression. The most desirable network usually is that which requires the smallest number of components.

An example of simplification utilizing a few of the laws is given in the problem below.

Simplify the expression

$$\left[\overline{(\overline{A + B}) + (\overline{A + C})}\right]$$

Applying DeMorgan's theorem produces

$$(\overline{A + B}) \cdot (\overline{A + C})$$

Applying the law of double negative produces

$$(A + B)\ (A + C)$$

Applying part 2 of the distributive law produces

$$A + BC$$

Figure 10-9 shows logic diagrams of the circuit configurations which represent these two Boolean expressions. The unsimplified expression is shown in (A), and the simplified expression is shown in (B). The truth table in figure 10-9 (C) shows that the relationship of input and output signals has not changed,

Table 10-5. —Laws of Boolean algebra.

Law	Part 1	Part 2
Identity	$A = A$	$\overline{A} = \overline{A}$
Intersection	$A \cdot 1 = A$	$A \cdot 0 = 0$
Union	$A + 1 = 1$	$A + 0 = A$
Complementary	$A\overline{A} = 0$	$A + \overline{A} = 1$
Idempotent	$AA = A$	$A + A = A$
Commutative	$AB = BA$	$A + B = B + A$
Associative	$A(BC) = ABC$	$A + (B + C) = A + B + C$
Distributive	$A(B + C) = AB + AC$	$A + (BC) = (A + B)\ (A + C)$
Absorption	$A(A + B) = A$	$A + (AB) = A$
Dualization (DeMorgan's theorem)	$\overline{AB} = \overline{A} + \overline{B}$	$\overline{A + B} = \overline{A} \cdot \overline{B}$
Double negative	$\overline{\overline{A}} = A$

while the simplification has changed the physical appearance of the electrical network. The final outputs of the two expressions, (A) and (B), are equal, using the same inputs.

For an extensive coverage of Boolean algebra, including other simplification techniques, refer to Mathematics, Vol. 3, NavPers 10073. Chapter 2, Number Systems; Chapter 3, Boolean Algebra; and Chapter 4, Simplification Techniques and Applications are applicable to the study of digital computers. Other chapters are devoted to the mathematics of analog computers.

BASIC CIRCUITS

Many of the basic circuits used in digital computers are conventional electronic circuits generally applicable to electronic equipment. These circuits include amplifiers, timing signal generators, pulse generators, waveshaping circuits, and time delay circuits. These general circuits will not be discussed in detail in this chapter. The circuits presented are limited to those logic circuits which are peculiar to digital computers.

These logic circuits are the high speed electronic switching circuits that perform the functions of storing information signals and of performing logical operations on these signals. The storage circuits are discussed in a later section of this chapter. The circuits which perform the logical operations previously discussed sense the input conditions and provide an output only if certain input conditions exist. They can be classified generally as gate circuits, which may employ vacuum tubes, diodes, transistors, tunnel diodes, semiconductor rectifiers, or magnetic cores.

By opening some gates and closing others, a signal may be routed over a predetermined course. The computer, when reading input data and performing its operation, is concerned only with the arrangement of pulses of voltage or current. This is the method that designers have employed to cause the computer to perform predetermined operations, and also the method by which the computer performs those operations. The control unit determines the sequence in which the gates are to be operated, and it receives its instructions from the input data. The input data, in turn, is supplied by the programer.

The circuits discussed in this chapter are logic circuits which may be utilized to provide a "yes or no" or "true or false" answer to specific questions. These bistable circuits may be gates which are either conducting or cut off, or they may be circuits that will always be at one of two specific voltage levels. In either case, the two outputs may be considered as being either negative or positive with respect to each other. Normally, these output levels are used to represent binary 1's or binary 0's. Insofar as circuitry is concerned, it is possible to use either voltage state or level to represent either binary digit. Therefore, it is essential to the understanding of circuitry that some distinction be made regarding the system of logic in any specific application.

The term POSITIVE LOGIC is used to denote circuitry in which the voltage level utilized to represent a binary 1 is positive with respect to the level which represents a binary 0. The term NEGATIVE LOGIC is applied to circuits in which the voltage level representing a binary 1 is negative with respect to the level which represents binary 0. The circuits presented in this course which employ negative logic will be specifically identified as negative logic circuits.

Another convention which is sometimes used defines positive and negative logic in terms of the voltage level used to activate the gate circuits.

NOT Circuits

The NOT circuit, also known as an inverter, is nothing more than a normal gate amplifier stage that produces an inversion (negation) of the input signal and has unity gain. Figure 10-10 illustrates two NOT circuits. The waveforms and logic diagram symbols for these two circuits are given.

In the vacuum tube circuit shown in (A), the triode is biased beyond cutoff with no signal applied. A positive pulse input causes the tube to conduct, and the output voltage level changes to a relatively negative value. (A vacuum tube NOT circuit using negative logic in the same configuration would be biased for heavy conduction when no signal is applied, and negative inputs would cut the tube off.)

In the PNP transistor circuit shown in (B), the transistor is biased to cutoff by the divider (R2 and R3), making the base positive with respect to the emitter. The input signal is divided by R1 and R2 to make circuit gain

890 888

Figure 10-10.—NOT circuits. (A) Vacuum tube circuit; (B) transistorized.

unity. Note that the input signal must be negative to cause conduction; therefore, this circuit represents a negative logic NOT circuit. The logic symbols presented here indicate, by the use of a small circle on the triangle, the low level or negative state; that is, in (A) the inversion is from a positive going to a negative going signal, while in (B) the reverse is true.

It should be noted at this time that any circuit which inverts the signal and produces unity gain falls under the definition of a NOT circuit. One common device used in this manner is the unity transformer.

OR Circuits

An OR circuit is the logic circuit having two or more inputs and producing an output if any one or more (or all) of the inputs are placed in the required signal state. Figure 10-11 shows two types of OR circuit.

In the block symbol, four inputs are illustrated. This is not necessary—many OR circuits are used which have only two inputs. In an OR circuit, any practical number of inputs may be used. The truth table in this figure also illustrates that a two-level gate with 4 inputs may have 16 different input signal combinations ($2^4 = 16$). The waveform drawing does not show all possible input combinations, but enough combinations are shown to convey the idea that with any positive input, a positive output will result.

The vacuum tube in the circuit shown in (A) is biased to cutoff when there is no signal applied. The inputs are each fed through a resistor to the grid of the tube. The resistor in the signal path decreases the interaction between the individual input lines. A positive signal applied to any one or more of the input leads causes the tube to conduct, and (by cathode follower action) a positive signal is taken from the cathode.

Figure 10-12. —NOR circuit.

Figure 10-11. —OR circuits.

The positive logic diode OR circuit shown in (B) can be examined using the truth table as shown. When any one or more of the inputs receive a positive signal, the diode receiving that input conducts. A signal is impressed accross R_L, resulting in a positive going waveform at the output.

NOR Circuits

Figure 10-12 shows a transistor type OR circuit which also includes the negation function of the NOT circuit. A circuit that performs both of these logic functions is called a NOR (NOT OR) circuit, as explained in the previous discussion of logic operations.

With no input signal applied, the NPN transistor is biased to cutoff by the reverse bias between the emitter and base. A positive input pulse causes saturation conduction of the transistor, producing a negative going output pulse at the collector. The triode in figure 10-11 (A) could be changed to a NOR circuit by replacing the cathode output with an output from a plate load resistor. Similar circuits could be arranged for negative inputs by biasing an NPN transistor to saturation or by biasing a PNP transistor to cutoff.

AND Circuits

An AND circuit is similar to a coincidence circuit in that it requires that all inputs meet a set of prescribed conditions in order to produce an output. Two transistorized versions of AND circuits are shown in figure 10-13.

In figure 10-13 (A), two PNP transistors are connected together at the collectors and emitters to form an emitter follower type circuit. There are two separate input terminals for the base signals. Initially both transistors are biased to saturation conduction, and nearly all of the collector voltage is dropped across R_L. Positive signals fed to the base of each transistor will cut off the respective transistors, but both transistors must be cut off in order to produce an output. When both of the transistors are cut off simultaneously, the output terminal voltage will go in a positive direction.

The circuit shown in figure 10-13 (B) is a negative logic AND circuit. With no signal applied, each transistor is cut off. During operation, all transistors must be activated together. If any one or more of the transistors remain cut off, there is no current path through the series connected emitter collector circuits. If all transistors are driven into conduction (by negative signals applied to the bases), the output at the emitter terminal will increase in a negative direction.

Figure 10-13. —AND circuits. (A) Positive logic; (B) negative logic.

NAND Circuits

The NAND (NOT AND) circuits are shown in figure 10-14. Both of these circuits combine the AND function and the NOT function.

Figure 10-14. —NAND circuits.

In (A) the PNP transistors are biased for saturation conduction in the absence of signals. If positive signals are applied simultaneously to both bases, both transistors will be cut off (the AND function). When cutoff occurs for both transistors, the collector voltage (output) goes relatively negative. This signal inversion is the NOT function.

In (B) the NPN transistors are also statically biased for saturation conduction. When both transistors are cut off by coincident negative signals, the output voltage from the collector is relatively positive. This is a negative logic NAND circuit.

Comparison of these circuits will illustrate the similari[illegible]d the differences between

positive and negative logic circuits, and the AND, OR, and NOT functions. In transistor logic circuits, if the output signal is taken from the emitter, there is no inversion of the signal; if the output is taken from the collector, the circuit is capable of performing the NOT function. In series connected transistors, all transistors must conduct if the output signal is to be the result of conduction. If the transistor is cut off under no-signal conditions, a definite polarity is required to cause conduction; if the transistor is conducting, the opposite polarity input is required in order to cut it off. PNP and NPN transistors react differently to the same conditions of biasing and signal.

When studying any specific computer circuitry to determine the theory of operation, the factors discussed in the previous paragraph must be taken into consideration. To illustrate this statement, refer to the circuit shown in figure 10-14 (A). As shown, it is a positive logic NAND circuit. By moving the output resistor (R_L) to the emitter circuit, the NOT function is removed, and the circuit becomes a positive logic AND circuit similar in operation to figure 10-13 (A). If the PNP transistors are biased at cutoff, negative inputs are required to produce conduction. However, since conduction of either transistor would produce an output, the circuit becomes an OR circuit (or a NOR, depending upon the connection of the load resistor).

INHIBITOR Circuits

An INHIBITOR may be formed by using a combination of any of the NOT AND circuits, with the NOT circuit in one input leg of the AND circuit. This operation can also be performed by other circuits. The circuit in figure 10-15 (A) provides the inversion (NOT function) by placing a transformer in the input leg of diode D3.

Diodes D1 and D2 are forward biased, allowing them to conduct. This places the output voltage at a low level (binary 0). Diode D3, however, is biased so that the diode is cut off with no signal applied to input C. With a signal applied to either input A or B, either D1 or D2 will be cut off; however, the other will continue to conduct, holding the output at a low potential.

When inputs A and B both have a signal applied, with no signal applied to input C, both D1 and D2 will be cut off and the output will rise to a high positive potential (binary 1).

If a pulse is applied to input C, the pulse will be inverted across the transformer. This will overcome the bias on D3, allowing it to conduct, holding the output to a low level regardless of the state of the other inputs.

Figure 10-15. —INHIBITOR circuits.

894

Another circuit which will perform the INHIBIT operation is shown in figure 10-15 (B). The circuit employs an NPN transistor with the emitter grounded. Note that the emitter base circuit is biased in the reverse direction; therefore, the transistor will be normally cut off.

If a positive pulse is applied to input. A, current flow through the load fresistor will produce a corresponding signal at the output terminal, when no input is present at input terminal B.

If, however, a positive pulse appears at input B at the same time there is one present at input A, this input would overcome the reverse bias and the transistor would conduct to saturation. When at saturation, the transistor is effectively a short circuit and the input pulse at A would be effectively lost; thus it would not appear in the output. In this fashion, a pulse applied to input B INHIBITS the appearance of a pulse at the output terminal.

ARITHMETICAL FUNCTIONAL CIRCUITS

The circuits previously explained as individual circuits are all combined in the computer to operate as an integrated system. Each circuit on a schematic is normally shown in symbol form. As yet there is no universally used system of symbols for computer block diagrams. The symbols given in MIL-STD-806B are the ones used in this chapter. In the inhibitor circuit, note that one of the inputs is terminated in a small half-circle instead of an arrowhead. This symbol indicates that inhibitor pulses are applied to the circuit.

Adders

Adders in digital computers use combinations of AND, OR, NOT, and INHIBITOR circuits to perform the functions of addition. When adding numbers, it is often necessary to CARRY a number to the next column. For example,

$$\begin{array}{r} ① \\ 45 \\ +\,19 \\ \hline 64 \end{array}$$

It is the carry function of arithmetic (the 1 encircled) that necessitates complex circuits in computers. Were carries not needed, a simple OR circuit could easily add numbers, for it has an output pulse whenever pulses appear at either or both inputs. Figure 10-16 shows the OR circuit and block diagrams of two other circuits which are used in construction of an adder. All of the circuits shown could perform the addition function, were a carry not required.

A binary word appears as a train of pulses with spaces to indicate 0's. In an adder, a pulse train applied to one input will be added to a pulse train applied to another input. In figure 10-16 (A) the OR circuit has produced an output pulse each time a pulse appeared at either or both of the input lines. However, the output word of the two binary inputs is not the correct sum. The pulse train at input 1 is a binary 0101101 (45 in decimal notation); at input 2 the binary word is 0010011 (decimal 19). Adding these two inputs should give binary 1000000 (decimal 64). The actual output word is 0111111, which is 63 in decimal notation. The error is caused by the fact that this circuit cannot carry a digit.

The quarter adder (EXCLUSIVE OR circuit) shown in figure 10-16 (B) is another of the circuits which can generate the sum of two inputs but cannot perform the carry operation. With the circuit inputs as shown in (B), both inputs to the AND circuit receive a 1 as the first digit applied. This results in a 1 in the output. This pulse is applied to the inhibitor as an inhibiting pulse and prevents an output when the first 1 pulse from the OR circuit is applied. In this case the output of the quarter adder is 100. This is not the correct sum of the inputs (101 and 001), as is shown in the example below.

Binary addition is performed as follows when a carry is involved:

$$\begin{array}{r} ① \\ 001 \\ \underline{101} \\ 110 \end{array}$$

In the first column a 1 is to be added to a 1—the sum is 0 with a 1 carry. The 1 carry is shown encircled over the second column; adding the 1 carry to the two 0's in the second column produces a sum of 1, with no carry; in the third column a 1 added to a 0 produces a sum of 1. Thus, 110 is the correct sum of the two inputs to the half adder; but because the inhibiting pulse of the

895 328

Figure 10-16. —Adder circuits with no carry.

carry is in the first place instead of the second place, a false sum of 100 is produced.

A half adder is shown in (C). It utilizes the same circuit configuration as the quarter adder, with an additional output line. This second output (from the AND gate) is the carry output. The difference between the quarter and half adder is the carry output of the latter. NOTE: The half adder is not capable of performing addition involving the carry function. It only generates the carry output which is utilized by additional circuitry to perform the complete addition function.

One of the circuits that must be discussed in connection with adders is the delay circuit. The delay circuit functions much like a conventional delay line. It delays a pulse train for the duration of one pulse; that is, all the pulse in a train advancing from left to right are moved one place to the left. Thus, the binary number 001 applied to a delay circuit becomes 010 in its output. The delay circuit permits the carry function of arithmetic in adders. It is used with a combination of OR, AND, and NOT circuits to make up a full adder circuit. A full adder consisting of two half adders and a delay line is shown in figure 10-17.

The inputs to the adder in figure 10-17 are the binary numbers 0011 and 0101, and the correct sum of these two numbers is binary 1000. The circuit operation to perform this addition is described in the following paragraphs.

For ease of explanation we will call the pulse sequence time 1, 2, 3, and 4, starting with the least significant bit (digit farthest to the right). Recall from the previous discussion that the output of the half adder will be a 1 on the sum line (total) and a zero on the carry output line when only one input is present. If both inputs are present the output will be a zero on the sum line and a 1 on the carry line.

The inputs shown to the first half adder give the outputs 0110 and 0001, as shown in the figure. The output train on the A line (0110) is the A input to the second half adder. The delay line, however, causes the B input of the second half adder to differ from the B output of the first half adder as shown in figure 10-17.

The second half adder inputs at time 1 are 0 on the A line and 0 on the B line, due to the delay line. The sum and carry outputs are both 0 at this time. At time 2 the A input is 1, the B input is the delayed 1, and this gives a sum of 0 and a carry of 1. At time 3 the A and B inputs are again 1 and the outputs are the same as for time 2. At time 4 the A input is 0 and the delayed B input is 1. This gives an output sum of 1 and a carry of 0, for the correct sum to the addition problem.

Subtraction in Computers

Subtraction in computers is performed by employing the same circuits that have been discussed; namely adders, inhibitors, and delay lines. They are not connected the same as when used in adders; however, each circuit performs its operation in exactly the manner that has been described. The following discussion is a simplification used for illustration.

Figure 10-18 (A) shows the basic subtractor circuit. It is shown only for the purpose of illustrating the subtraction principle; this circuit must be combined with adders and delay lines (as shown in (C)) in order to function as a subtractor and give true answers. In (A) the inhibitor produces a true remainder when no "borrow" is necessary. In (B) however, the remainder is false because the basic circuit cannot perform the necessary borrow

Figure 10-17.—Full serial adder.

Figure 10-18.—Binary subtraction circuits, block diagram. (A) Basic—no borrow needed; (B) basic—borrow needed but not provided; (C) subtractor that borrows.

function. The subtracting circuit in figure 10-18 (C) shows the arrangement necessary to perform a borrow function.

In this circuit it is desired to subtract 01 from 10. At I1 (inhibitor No. 1), the inhibiting pulse in the subtrahend arrives when there is no pulse in the minuend to inhibit, so the 10 passes through the inhibitor to the adder. I2 has the same inputs applied, except that they are reversed so that the minuend (10) becomes the inhibiting input. Here again, the inhibiting pulse arrives when there is no input pulse to inhibit, so the 01 input at I2 is passed through and appears at two places—the delay line and the adder. At the adder, the two inputs are added to produce 11 at the input to I3. I3 also has an inhibitory pulse applied from the delay line which has been shifted one place to the left to become 10. This time the inhibiting pulse at I3 inhibits the second pulse of the input to produce 01 at the output of I3. This is a true remainder. By shifting the output of I2 one place to the left, a borrow function was effectively performed.

The circuit just described is capable of performing only one borrow function. For subtraction involving multiple functions of borrow, additional adders and delay circuits must be incorporated, or the more practical shift register may be used to shift the necessary pulses as required.

SUBTRACTION WITH COMPLEMENTS.—Another method of subtraction widely used in digital computers involves complementing the subtrahend and adding the numbers. The main advantage gained by using this system is that computers can perform both addition and subtraction with the same arithmetic circuits.

Any number system has two types of complements that are useful in computers—a true complement and a radix-minus-one complement. (Remember that "radix" is another word for "base" in number system terminology.) The true complement is formed by subtracting each digit of the number from the radix-minus-one value (9 for decimal numbers and 1 for binary numbers) of the number system and then adding 1 to the least significant digit of the number formed. A decimal system number's true complement is known as the 10's complement, and a binary system number's true complement is known as the 2's complement. As

898

an example, find the 10's complement of the decimal number 13:

```
  99
 -13
  86
 + 1
  87
```

Therefore, 87 is the 10's complement for the decimal number 13. The 2's complement of a binary system number, such as 10101, is found by subtracting each digit from 1, which is the radix-minus = one value, and adding 1 to the number formed. The 2's complement of the binary number 10101 is:

```
  11111
 -10101
  01010
 +    1
  01011
```

However, it can be accomplished faster by changing each 1 to a 0 and each 0 to a 1, and adding a 1. Such an operation in a digital computer is usually accomplished by inverting all the pulses, or lack of pulses, in a pulse train that represents the number, and adding a pulse that represents a 1.

The radix-minus-one complement of a number is formed by subtracting each digit from the radix-minus-one value, but a 1 is not added to the least significant digit of the number formed. The radix-minus-one complement of the decimal number 13 is 86, and 01010 is the radix-minus-one complement for the binary number 10101. These are known as the 9's and 1's complements, respectively.

Since the digital computer uses binary representation of quantities, the use of only the 2's and 1's complements will be illustrated. Decimal numbers are converted into binary numbers before operations are performed by the arithmetic circuits.

Subtraction using the 2's complement involves forming the 2's complement of the subtrahend and then adding this true complement to the minuend.

Normal binary	2's complement
1101	1101
-1011	+0101
0010	10010 = 0010
	(Drop the 1 on the left, which is the carry.)

The answers, after dropping the 1 in the answer of the complemented case, are identical.

Subtraction with the 1's complement is very simple because the 1's complement is easier to form than the 2's complement.

Normal binary	1's complement
10110	10110
-01011	+10100
01011	101010
	+1
	01011
	(Add the 1 on the left, which is the carry, to the other five digits.)

Again, in this case by adding the carry of 1, the answers are the same. Note that subtraction with the 1's complement in this example is much easier than normal binary subtraction. Also, note that only an inverter stage is necessary to form the 1's complement of the subtrahend electronically.

Counting by Flip-Flop

The modified Eccles-Jordan multivibrator is the circuit used, in conjunction with other circuits, for counting. It is a two-state oscillator that remains in either of its two conditions until a pulse is received to flip it to the opposite condition. The output, if taken from the plate of one tube, will be a positive voltage representing a 1 in one condition and a low voltage representing a 0 in the other condition. Each pulse input to the stage will flip it to the opposite condition, so two pulses are required at the input to produce one pulse at the output.

The simplified flip-flops (FF's) in figure 10-19 are arranged to show the basic arrangement of counters. Should you require a refresher on the theory of the plate coupled multivibrator, refer to Basic Electronics, NavPers 10087-B.

Counting by FF is possible because of the characteristic that requires two pulses in to produce one pulse out. In the figure, note that the input to the counter chain is on the right side of the figure. This arrangement is used because the indicator lamps of each stage will be read as binary numbers. If the lamp in the second stage is lighted and the lamp in

Figure 10-19.—Basic counter.

the first stage is not lighted, the binary indication is 10, or decimal 2. If both lamps are lighted, the binary number is 11, or decimal 3. Additional stages are necessary to count a higher number than three, and each of these additional stages from the input represents a power of two.

Note also that the grid of each tube labeled V2 has a reset provision with a positive voltage that is applied by closing the switch. Before any counting is begun, all the V2 tubes in the chain are caused to conduct by a momentary closing of the reset switch, and all indicator lamps register 0. This is the reset condition.

The grids of both tubes in each stage are tied together so that any negative signal applied appears on both grids simultaneously. The diodes in the grid inputs prevent a positive signal from reaching the grids. They respond only to negative pulses.

Assume that the circuit has been reset so that all V2 tubes are conducting. In this state the plate voltage is too low to light the neon lamp, and all lamps register 0. The first negative pulse applied to the inputs of both tubes of the first stage flips the circuit to the opposite condition; V1 now conducts, V2 cuts off, and its plate voltage rises and lights the lamp to indicate 1. The positive rise of voltage is capacitively coupled to the second stage, but the diodes prevent the positive pulse from having any effect. Reading the two indicator lamps after the first pulse has been applied produces binary 01, meaning a count of 1. The second negative pulse that arrives causes the first stage to flop back to the reset state; V1 cuts off; V2 goes into conduction, its plate voltage drops, its lamp goes out; and the negative pulse is coupled to the second stage. This negative pulse flips stage No. 2 to its opposite state and lights its lamp. The lamps now register binary 10, which is decimal 2. Note that two pulses were required at the input to produce one pulse out.

In late-model computers, the FF circuits use transistors, and a long chain of such stages can be built into a small space. Each additional stage makes provision for a higher counting capability. Each succeeding countdown circuit, as the FF is sometimes called, "counts" in the same manner, or scales by two. Each additional stage also scales by two; a two-stage FF, as shown in the figure, scales by four; a three-stage unit will scale by eight; a four-stage unit will scale by 16; etc.

900 608

The same circuit, with only slight modification, could be used to count positive inputs.

Accumulator

The accumulator of a computer is the unit in which storage operations are performed. Basically, it consists of a memory section called a register (discussed later in this chapter) and is used in connection with an adder. The register is a group of FF and memory elements that route and store data. The adder has been explained previously. The A-register performs two functions: it furnishes the stored augend to the adder and stores the sum of an addition operation. (See fig. 10-20.)

In this connotation, the "augend" is the subtotal. In each progressive addition, the total of the previous addition is fed to the adder (as the augend), and is then combined with the new data to furnish a new total which is stored in the A-register. For example, the A-register holds a number, say 4, and it is to be added to another number, say 3; then both the 4 from the A-register and the 3 from the addend register are sent to the adder. The sum of the addition, 7, is sent to the A-register and remains until more data is to be added to it. The A-register accumulates data for arithmetic operations.

Figure 10-20.—Accumulator.

Clock Pulses

An idea which is basic to most digital computers is that of a uniform rate of counting (synchronous operation). To provide for this feature, a CLOCK, or master timer, is employed. This circuit produces or controls the rate of timing pulses. The interval between the pulses determines the period of time during which an event can occur. If a signal is delayed for a number of pulse intervals and then fed back to the input of an AND circuit, that signal will be continuously regenerated, and may be used to store data bits (binary digits) according to the length of the delay. Since the AND circuit will produce an output only when both input signals are present, the repetition of the pulse permits the transfer of data during that interval. The delay may be of any convenient length, and may be used to store any number of digits. Therefore, such an arrangement is entirely practical.

PULSE RESHAPING.—In addition to serving as the master timer for the computer, the clock pulses are also used in pulse reshaping circuits.

As pulse trains pass through various circuits of a computer, the rise and fall times of the pulses usually increase; the amplitude may decrease; and the pulses are delayed in time as they move through circuits. The clock pulses, which are usually available at several points in the computer and have a choice of pulses that are shifted in time by 1/4 cycle, are used with a reshaping circuit to restore the shapes of numerical or instructional information pulses within the computer.

If the information pulses to be reshaped occur at the same time as an available clock pulse, a simple AND circuit can be used to reshape the pulse. Figure 10-21 (A) shows clock pulses and deteriorated pulses applied simultaneously to terminals A and B, respectively, of an AND circuit. In a properly designed circuit, the output is produced only during the time interval t_1 to t_2. The rounded top of the output pulse can be clipped in a succeeding amplifier stage.

Instances will occur where the deteriorated pulses to be reshaped are no longer in time synchronization with the clock pulses. In these cases, the circuit shown in figure 10-21 (B) can be used to reshape the pulses.

The deteriorated pulses and clock pulses are applied to terminals A and B, respectively. The deteriorated pulses pass through the OR circuit and, together with the clock pulses,

901 809

Figure 10-21.—Reshaping circuits.

cause an output from the AND circuit during the portion of the time that they occur simultaneously. Now, if there were no regenerative (positive) feedback from the amplifier output, the output would be representative of only the overlap time of the deteriorated and clock pulses. However, the positive feedback and the clock pulse keep the AND circuit functioning, producing an input to the amplifier until the clock pulse ends. This produces an output pulse that is identical to the clock pulse. This circuit allows a pulse that is not in time sequence with a clock pulse to be reshaped, but there must be some overlap in the duration of the two pulses.

STORAGE (MEMORY)

Although there are many different systems for data storage used in digital computers, this discussion will be limited to some of the more common magnetic systems and the shift register. The magnetic systems employed are DYNAMIC; that is, the stored information must be moving in order to be used. For this reason it becomes necessary to recirculate the signal over a given path. If the signal were not recirculated, the end of the storage medium could be reached before the complete data storage process was completed. Recirculation is accomplished by rotating a closed loop, and will be clarified later in this section.

Since many computers require the storage of (and access to) more bits of information than can be accommodated in a single unit, the use of multiple memory units has become a common practice. The use of more than one memory unit requires that inputs be supplied directly to each unit. Items that are to be stored periodically (or items that are time dependent) are supplied to the circulating memory under the control of the internal program.

Magnetizing the Memory Unit

The magnetization curves of those ferrite materials which are commonly used in computer memories are essentially square, as shown in figure 10-22 (A). However, the heavy line

Figure 10-22.—Magnetizing ferrite materials. (A) Idealized B-H curve; (B) more realistic representation; (C) recording method, showing distortion; (D) recording levels.

which indicates the loop represents the ideal case of a symmetrical magnetizing force. This situation does not apply in computers. A more realistic representation of the hysteresis loop is shown in (B). A complete representation of the magnetizing process would show that successive B-H loops do not exactly close; but each time a new loop is formed, it more closely approaches the ideal loop, until the difference becomes undetectable after a few cycles.

RECORDING.—The process of recording a 0 or a 1 on a magnetic medium involves two opposing problems:

1. To obtain the highest practical packing density (storage of the maximum number of items in the minimum space).

2. To maintain reliability (ability to recognize and use the stored data).

In order to obtain the highest packing density, considerable distortion must be tolerated.

A saturation amplitude signal is normally used in recording digital data, and this results in a gross distortion of the input signal. Figure 10-22 (C) illustrates the type of distortion involved. When the magnetic recording material is saturated, the output winding detects no change in flux, and therefore produces no output signal. Signals are produced only when the material is going into or out of saturation. The magnetic airgap (shim) dimensions determine the amount of material needed to record a single data bit.

SIGNAL AMPLITUDE.—The amplitude of signals recorded may be two-level or three-level, depending on whether a condition of zero magnetization is allowed to exist other than momentarily. Figure 10-22 (D) is an idealized representation of the binary number 10110 (decimal 22). The top waveshape represents the two-level signal, and the center waveshape represents the three-level signal. In the three-level system, note that the zero magnetization condition exists during the latter half of each data bit, and that the polarity of the magnetization is reversed for the 0 or the 1 digits.

In a third system of recording (shown in the bottom waveform of figure 10-22 (D)), no change of output is permitted to occur when succeeding digits are the same; therefore, no playback signal appears at this time. This is called the NON-RETURN-TO-ZERO method of recording. With a long series of 1's, counting the time intervals is made possible by the use of clock timing pulses. A separate recording track is usually devoted exclusively to the recording of these synchronizing signals.

READOUT.—Since the readout signal waveform differs greatly from the reading signal, additional circuitry is frequently used to restore the signal to its original shape. This circuitry normally consists of a saturation amplifier and clippers, or reshaping circuits such as those discussed earlier.

Memory Drum

Since many computers have magnetic memory units that move under heads, the information stored in the various channels can be changed as an operation progresses; that is, during the time that a problem is being solved—such as the bomb release point—some of the items of data will be varying and must be changed as the problem progresses. The heads of pertinent channels will be used to erase and rewrite information in those channels as required.

The magnetic drum is an aluminum cylinder coated with a magnetic material arranged in strips or tracks encircling the drum. Heads for writing or reading from the drum are mounted so that the drum rotates past and in close proximity to them. (See fig. 10-23 (A).) The heads are used to magnetize spots along the surface of the tracks when data is fed into the computer, and to pick off data as magnetized spots cause a pulse to appear at their outputs. This action is quite similar to that of a tape or wire recorder, since the portion of the revolving drum that passes under each head can be thought of as a ring or band of magnetic tape.

Figure 10-23 (B) shows how channels appear on the magnetic drum. In order to place the maximum number of heads over the drum, the heads are staggered in position as indicated in (C). Each pickup head can be considered as representing a channel of the rotating drum. Each channel is capable of storing approximately 80 bits per inch.

Magnetic memory drums vary greatly in capacity and operating speed. Speeds of 3,000 to 17,000 rpm and diameters of 4 to 12 inches are quite common. Access to data stored on the drum depends on the rotational speed and the location of the particular data desired. When the desired bit has just passed the head, the access time is maximum (1 revolution). If the desired bit is under the head, access time is nearly 0. Thus for the general case, average accesss time is 1/2 revolution. By improved programming methods, this access time may be further reduced. Average access times in practical airborne computers range from 2 to 10 milliseconds.

The drum shown in (D) includes a quick access band, each track of which comprises several circulating loops of the type shown in (E). These loops waste that portion of track (if any) which is not between the two heads which comprise a loop.

Each channel on the drum is identified, and the location (address) of each bit or word is identified. The channel may be thought of as resembling a motion picture film, with block separations to locate a specific word or bit. The address of a specific binary word is identified as to its channel, block and location within the block. The blocks will, of course, be very small as compared with the film.

Many bits are recorded in each block of each channel; and since the bits pass under

904 606

Figure 10-23.—The magnetic memory drum unit. (A) Read-write head; (B) magnetic drum; (C) arrangement of heads on drum; (D) arrangement of tracks on drum; (E) read-write circuit, block diagram.

the head one at a time, some method of identifying the start of a word must be provided. The first channels of the drum have magnetized sectors that provide for positive location of a word or digit within a word. These sectors usually contain pulses used for timing, location of words or word groups, word separation, and bits within a word. The timing pulses synchronize the actions of the other channels. In this manner, all the data on all

channels is in synchronism with the timing pulse; and if the drum speed varies, every calculation or other operation of the computer varies accordingly. When this feature is incorporated, drum rotational speed is not excessively critical.

Information and instructions are placed into the computer by an operator (known as the programer). He must determine exactly what operations the computer is to perform, plan the sequence of these operations, and prepare a PROGRAM for the computer to follow. The magnetic drum in airborne computers is normally programed for specific problem, and is CLEARED of data after the problem is finished and before the next problem is begun. Each new problem requires that new data be programed into the drum. Programing is discussed later in this chapter.

Ferrite Core Memory Element

Another type of memory device is the ferrite core. Its principle of operation is similar to that of magnetic amplifiers (discussed in chapter 9 of this course), in that it is magnetized with a polarity corresponding to the direction of the magnetizing force. The magnetizing force required is small; a single conductor passing through the core performs the function of a winding.

A magnetizing force applied in one direction magnetizes the ferrite core with a polarity that represents a binary 1, and when applied in the opposite direction causes the opposite polarity which represents a binary 0.

Ferrite cores are small rings of magnetic material, with typical diameters of approximately 0.05 inch. Figure 10-24 is an enlarged drawing of a section of a ferrite core matrix. A MATRIX is made up of many ferrite cores connected as shown in the figure, and arranged it in a flat panel inside a frame, with wires leading out for easy attachment. Very short access times (10 microseconds or less) are common, because modern high speed semiconductor switches make parallel access practical.

The arithmetic and memory units of a general purpose computer contain many of these matrices. Each core is capable of storing only 1 bit, so a matrix of 250 cores can store only 250 bits. Mutliplying the number of matrices by the number of cores per matrix gives the number of bits that a computer can handle.

In the figure, each core has three "windings." The wires that cross at right angles are used to magnetize the core, Using coincident current techniques, any single core may be selected for readin or readout. By passing a current through both the horizontal wire and the vertical wire which pass through a given core, the two fluxes may be made to add and to just exceed the threshold value necessary for switching magnetic polarity of the selected core. Each horizontal wire and each vertical wire pass through an entire string of cores. The only core affected, however, is the core at the intersection of the two wires that have the pulses applied. As an example, locate the junction of line B and line 2 on the diagram in figure 10-24. If both line B and line 2 have pulses applied, only core B2 will be affected, because the magnetizing effect of only one is not sufficient to cause the magnetization of the other cores to switch to the opposite polarity.

The use of a third (sense) winding permits the sensing of the switching of the core. If interrogated by coincident pulses, the core will switch and the change of flux will induce a pulse into the sense winding. The polarity of this induced pulse is an indication of the binary 1 or 0 that was stored in that core before switching occurred. When the core is read out, the binary bit in that core is lost. If it is desired to retain that bit, it is necessary to recirculate and reapply that bit to the core from which it was read out.

Single pulses will frequently be passed through a core when reading into or out of adjacent cores, but these cause no harm. In figure 10-25 the effect of single and coincident pulse is shown. In (A), a single pulse is shown to produce a negligible change in flux; in (B), coincident pulses are shown to produce a change in flux sufficient to switch magnetic polarity of the core. Residual flux is indicated by the saturation levels, N in one direction and S in the other.

TESTING.—A testing waveform of current may be used to determine the effect of repeated single pulses on a given core. In the ideal situation, a single pulse will have no effect, but this is not necessarily true in practice. To determine the effect of many single pulses on a given core, the waveform shown in figure 10-25 (C) is applied to the core to be tested. A pickup winding is used to sense the response of the core to the testing waveform, and the output of the pickup winding is applied to an

906

907

Figure 10-25.—Switching core polarity. (A) Single pulses; (B) coincident pulses; (C) testing waveform.

oscilloscope which is synchronized with the testing waveform.

The waveform is essentially divided into two parts. Part (a) in figure 10-25 (C) consists of a write pulse (w), followed by a single disturbing pulse (d) and a read pulse (r). Part (b) is similar, but includes a series of disturbing pulses instead of a single one. The response of the two reading pulses is an indication of the demagnetization of the core caused by several disturbing pulses (b) as compared with the single pulse in (a). If the response to the disturbing pulses is excessive, the core must be rejected.

Magnetic Disk

The rotating magnetic disk used with some airborne computers is increasing in popularity. Its function is the same as that of the drum, but the surface is flat like a phonograph record instead of cylindrical, and the tracks are circular instead of spiral as in a phonograph record. Spacing of the recording heads is maintained constant. Very high storage capacity is characteristic of this device, and the low mechanical inertia makes it appealing for airborne applications. Disk storage units have been built with 100 concentric tracks on each side of

each disk. Figure 10-26 indicates the construction of the disk type magnetic storage unit.

Magnetic Tape

Perhaps the most "familiar" type of storage is magnetic tape. The materials used for recording may be the same as those used for audio recording, except that a very high quality tape is required to avoid missing an occasional bit. Seven-channel tape (common in computer work) is usually 1/2 inch wide, and has a recording density of 100 to over 500 bits per inch. A 2,400-foot roll can store about 3 to 16 million characters. (This is less than the apparent maximum, because the gap between recorded sections of tape may be from 1/2 to 2 1/2 inches.) The tape must be brought up to operating speed before reading or writing is begun. Actual tape speed may be as high as 240 inches per second.

Since input and output devices are generally mechanical, it may be advantageous (both for speed and economy) to record the computer output at its optimum speed on tape, and later play it back at any convenient speed into the appropriate terminal unit. Similarly, a separate tape track may carry other data essential to the evaluation of the tape. Thus a flight performance monitor may furnish a complete log of equipment operation and performance, from preflight to postflight. In this instance, a low speed would be required, with data being fed into storage at regular intervals during the flight.

Figure 10-26.—Magnetic disk storage device.

Tapes produced by computers are used extensively for controlling other processes. Since the data is digital, it can be operated at various speeds, and even stopped, with no loss or distortion of data while other operations are performed.

Many techniques are available to overcome random data acquisition on tapes. These include use of multiple tracks, multiple read heads, etc. The chief advantage of magnetic tape is its ability to store millions of data bits inexpensively. Under ordinary operating conditions, magnetic tape is usable up to 50,000 times. Data on a used tape may be transferred to a new one. Temperature and humidity must be controlled, as variations may cause the oxide surfaces to crack. Since dust may cause a signal to be missed, extreme care in manual handling is necessary. Oil or moisture from manual handling may encourage the collection of dust.

Other Magnetic Devices

A readout device with characteristics similar to those of the ferrite core, but whose stored data is not destroyed in the reading process, is called the TRANSFLUXER. Figure 10-27 (A) shows that a second, smaller aperture is used to permit sampling and possible switching of only that portion of flux which exists around the small hole. During readout, this device does not switch all the flux contained in the core. The transfluxer may also be used for storing analog quantities.

The THIN FILM DOT ARRAY memory device (shown in fig. 10-27 (B)) promises very fast, compact, and inexpensive switching. Access time of 0.2 microsecond has been demonstrated. The magnetic characteristics of this thin magnetic surface are directional in nature; the film is easy to magnetize in one direction, but hard in a direction at right angles to that direction. The magnetization characteristic in the direction of difficult magnetization is essentially without hysteresis (instead of a B-H loop, it collapses into a line), but the B-H characteristic in the direction of easy magnetization is the familiar square loop.

Register

A registers is a device that provides temporary storage of a binary word during computation. Registers are composed of flip-flops

909

Figure 10-27.—Magnetic memory devices. (A) Transfluxer; (B) thin film dot array.

(FF's) and are generally found in the control and arithmetic units of digital computers. There may be several in a large computer; however, a simple arithmetic unit may contain only one or two. The number depends on the amount and variety of other storage facilities that are included. It is also somewhat dependent upon the speed with which the computer is designed to operate. A relatively long time is required for readout of a word from a magnetic drum memory; a shorter readout time is possible with magnetic core matrix type memory units. Generally, one or more arithmetic registers can be used to advantage in speeding up the computation.

Remember that a word is a group of pulses; each pulse, or lack of one, represents a bit; each bit represents binary digit whose value is 1 or 0. The chair of bits can be of almost any length. This group of pulses at the input unit can represent instructions, constants, and/or variables for the problem. In the actual arithmetic circuits, the pulse chains that represent the constants and variables for the problem are present. The instruction portion of the word is used to program the computer.

STORAGE REGISTER.—A storage register is used to store a word temporarily. Storage registers consist of a group of FF's capable of storing the maximum word length expected; they operate in the same fashion as counter FF's. Figure 10-28 represents a storage register which is capable of handling a four-bit word. The lower group of FF's comprise the register, and the upper group form and associated counter. Between the two is a group of AND circuits. (Note that the input to the counter is in serial form and the input to the register is in parallel form; therefore, it also forms a serial to parallel converter for the word. The counter is included in the set because of this function as a converter.) First, the word is applied to the counter. Later a read pulse is applied to the AND circuits. If the read pulse and the voltage at the 1 output of a particular counter FF agree in voltage levels, a 1 pulse is transmitted to the corresponding register FF. No signal is transmitted to a register FF if the 1 output of the corresponding counter FF is at a 0 voltage level or, in any case, until there is a read pulse applied.

Each register FF can store a single bit, representing a 1 or 0. Note that at the same time a 1 is represented by a 1 level of voltage at the 1 output terminal, a 0 voltage level is represented by the 0 output terminal. The output from the lower FF's (fig. 10-28) might be applied to the augend or addend terminals of a parallel adder circuit, the other word being supplied by similar means. If both the 1 and 0 leads are connected to other circuits, the condition is known as "double lead transfer" of information.

An extra bit is included in an information word to indicate the sign of the binary number. A three-bit word such as +110 would be fed into the counter or register as 0110, where the first 0 would indicate a positive number. A negative number would be 1110. Therefore, the circuits that handle signed words must have an extra FF to handle the sign bit.

A storage register and serial to parallel converter that does not use an associated counter is shown in figure 10-29. Delay lines (D) are used in this instance to provide the conversion from serial to parallel. Each delay line introduces a delay equal to one input pulse spacing,

810 808

Figure 10-28. —A four-bit register and associated counter.

Figure 10-29. —Storage register using delay lines.

Therefore, the first input pulse (the one shown at the left in the pulse train) arrives at A4 at the same instant that the last bit pulse is applied at A1. The input pulse spacing is the same as that of the clock pulses for serial form. Therefore the read pulse could be taken from the clock, but it must not be applied to the AND circuits before the last input pulse is applied to A1.

SHIFT REGISTER.—A shift register is a storage register in which the stored number can be shifted left or right with a shift pulse. (See fig. 10-30.)

The shift pulse are applied continually, using the same spacing as the bits of the word. Since the FF would be upset if two pulses occurred simultaneously, the shift is applied midway between bit pulses. The stages are coupled so that any particular FF is set to a 1 state only if the preceding one was reset to 0 by the shift pulse. The delay lines (which may be RC circuits) have a delay that is only a small portion of the spacing between pulses. The operation of the shift register is discussed in the following paragraphs.

Assume that the binary word 1101 (decimal 13) is to be stored and that all FF's have been reset to 0. The first 1 bit is applied and sets FF1 to 1. This does not affect FF2. A shift pulse then occurs that resets FF1 to 0; and FF2 receives, after a short delay, a pulse from FF1 that sets it to 1. Then the second 1 bit is applied to FF1, setting it to 1 again. Now both FF1 and FF2 are set to 1; and another shift pulse occurs, resetting them to 0. Shortly thereafter, FF2 and FF3 are set to 1. The next bit in the word is a 0 and has no effect on FF1. The following shift pulse resets FF2 and FF3 to 0; later FF3 and FF4 are set to 1. FF1 and FF2 now read 0. The last bit sets FF1 to 1. Shift pulses are stopped at this point, and binary word 1101 has been stored.

The application of four additional shift pulses causes the stored word to be read out the left side of the register. The contents can be read out to additional FF stages, to the memory unit, or to adder circuits. The output might also be returned to the input, through pulse reshaping amplifiers, to form a dynamic (circulating) type register.

If the register contains many more stage than there are bits in the stored word, the stored word can be shifted to the left and its changing value doubled by each successive shift. For example, if the word 1101 (decimal 13) is shifted to the left by 1 bit, the register will read 11010 (decimal 26). If 11010 is shifted to the left again, the register will read 110100 (decimal 52). Therefore, each left shift multiplies the register word by binary 10 (decimal 2). Note that the decimal point location in the register does not shift. In this case, it remains at the input terminal, or the right of the last stored bit.

Additional stages have to be switched into the right-hand side of the register before the word 1101 can be shifted to the right. Assume that 1101 is stored and it is desired to shift it to the right. The decimal point is fixed at the input terminal point. Now, additional FF's are switched into the right side of the register, and a shift pulse is applied. The register will now read 110.1 (decimal 6.5). Thus the stored word has been divided by binary 10 (decimal 2). Another shift pulse would produce 11.01 (decimal 3.25).

Figure 10-30.—Shift register.

912

ACCUMULATOR.—Of the various types of register found in an automatic digital computer, the type which has the capacity to store a word, then receive additional words and sum the total, is the most important. A register with these features is defined as an accumulator. It will most likely also incorporate left and right shifting features and be capable of dynamic operation. It will be able to provide this additional feature while handling the maximum computer word length. Figure 10-31 presents a simplified block diagram of a serial arithmetic unit and indicates the importance of the accumulator. The accumulator can receive or send information to the memory unit; the stages of the shift register can be added to the accumulator to form a double-length accumulator during multiplication and division; and the complement register can be complemented and its contents added to the contents of the accumulator.

PROGRAMING

A digital computer can add or subtract almost indefinitely, and with lightning speed. For this speed to produce meaningful results, the computer must be supplied with complete instructions before each operation. The speed, accuracy, and versatility of the computer are determined by the type of instructions provided and the manner in which they are given. These instructions will at times be specific information, such as a number that represents some item of data, and at other times will be a number that represents an instruction. For instance, the program may instruct the computer to carry out a sequence of operation as follows:

1. Select a specific item from a specific location of a channel and transfer it to the arithmetic unit.
2. Select another item from some other channel and transfer it to the arithmetic unit.
3. Compare the two numbers.
4. Place the larger of the two numbers in a specified address on a specified channel.

The program portion just described is a simple example used to show how a programer talks to a computer. The programer may not be concerned with the actual answer to the problem, but only that an answer will be produced and placed in the memory unit at a specified address. The computer may be instructed to perform the same operation over and over; and if any of the data changes, the solution will also change. The solution to this problem will probably be used in other calculations required in the overall operation.

The programer for a computer does not necessarily need to know the mechanical or electronic theory of a computer, but he does

Figure 10-31.—Simple serial arithmetic unit.

913

need to know its maximum capabilities, number of words per block, number of bits per word, number of channels, and access time.

The switching or routing system of signals in computers can be compared to a huge railroad yard where many trains are being routed through a maze of tracks. All the trains are controlled from a central point and move as directed by the controller. A train is formed by directing an engine to move through the maze of tracks in the yard, picking up one or more cars at designated points. The completed train then moves out of the yard as an integral unit.

The paths followed in forming the train were predetermined and directed in sequence by the controller. In a similar manner, the control unit of a computer will be the controlling device that does the switching, and the courses taken by the binary bits will resemble the tracks of the yard. In the output of the computer, the completed data will be analogous to the train.

The Program

When the programer makes a program for a computer, he determines the sequence of operations necessary for the solution of a problem. Many automatic functions are built into the computer, such as switching, counting, arithmetic operations, and others involving the special mechanics of arithmetic employed by computers. A program may be set up in such a manner that each operation is given a coded number designation, and the programer merely inserts the coded numbers as instructions to the computer. Programing is technically only one part of preparing a problem for solution by a computer. Actually there are four major steps, as shown in figure 10-32. These are numerical analysis, planning the sequence of operations, (programing), coding, and checking. These jobs are frequently referred to collectively as "programing."

NUMERICAL ANALYSIS.—Numerical analysis is the definition, in proper mathematical terms, of the problem to be solved. It is the science of reducing real problems into terms, quantities, and equations that a digital computer can accept. In all but the simplest problems, extensive numerical analysis may be required before the program can be written. How does one represent an integral or differential, a cosine, or a quality? Numerical tricks, approximations, and even arbitrary values must be used in order to translate these concepts into the discrete, numerical values required by the computer.

PROGRAM PREPARATION.—Normally problems are too long and too complex to encode directly from the mathematical analysis. Programing provides the shorthand, or guide, which makes it possible to translate the mathematical operations into the step by step operations required by the specific computer to be used. Programing is primarily the task of drawing flow charts, or block diagrams, and planning memory allocations.

A flow chart (illustrated in (B) of fig. 10-32) is essentially an annotated block diagram and is an organizational convenience. In addition to depicting the overall system logic, it shows the sequence of logic operations, the result of each choice, and the time and entrance point of all new data.

Although it is intended principally as an aid in writing the computer code, the flow chart is also an excellent troubleshooting and testing device. It has symbols to describe the various functions to be performed, to indicate a logical choice or optional sequence, and to show when a sequence is changed by new or modifying instructions. Additional symbols and conventions are generally used to simplify the diagram and to make it a more complete instrument for aiding the man writing the code. These symbols are not standard, but they are usually consistent in a given set of charts. Their main purpose is to transfer information from the designer to the coder or other users of the computer.

CODING.—Coding is the step by step transformation of the problem, as mapped out by the flow chart, into a final program written in the language of a particular computer. Coding is essentially a precise bookkeeping operation; each address, each digit, and every single command must be correct.

The coder, unlike the man who writes the flow chart, needs little knowledge of mathematics; he does not even need to understand computers. The only absolute requirement is that he adhere inflexibly to the rules as established by the design of the computer. Generally, in transferring from one type or model of computer to another, the coder must learn a new set of rules, a new computer language, or a new code.

CHECKING.—Checking, or verifying, is the final step in the preparation of a particular

915

computer problem. It is frequently performed automatically. The sole purpose of this step is to insure that the coder has made no errors. The coded program may be stored internally or externally. Storage will be semipermanent or permanent, depending upon the purpose and application of the computer.

INPUT AND OUTPUT METHODS

The primary application of plug-in units in large digital computers is to supply multiple input and output devices capable of being individually and/or collectively coupled to the computer. Numerous devices have been developed to take advantage of the speed of the computer; a few of these devices are described in the following paragraph.

All converters are essentially counting, weighing, or reading devices. The output of the converter should be compatible in form and time availability with the computer that is to use it. The speed, precision, and accuracy required of the measurement determine the type converter used. Since the majority of inputs to airborne computers are available in analog form, the analog to digital converter type input is used extensively. Devices of this type are available to convert most analog inputs to digital form with almost any desired degree of accuracy.

In the sample program just discussed, the values of a, b, and P_0 are variable (and possibly constantly varying) quantities which are available in analog form from aircraft instruments or from computer sections. The following paragraphs discuss briefly each of the quantities, fixed or variable, included in the problem:

1. Acceleration (a) is available from an accelerometer in some form such that the output of the device is proportional to (analogous to) the acceleration. It represents a change in velocity.

2. Velocity (b) represents the resultant of the combined airspeed and wind vectors, such as the AN/ASA-47 calculations discussed later in this chapter. Since velocity is variable during the flight, this quantity may be available directly from the computer, or it may be stored in an easily erasable memory circuit and corrected as the occasion demands.

3. The time interval (t) is determined by clock timing pulses. The shorter the time interval (and the more nearly constant the clock PRF), the more accurate the possible computations.

4. Position at time zero (P_0) indicates the position at the beginning of the time interval. At the beginning of the solution, this position may be inserted manually, or it may be made available to the computer from an automatic navigation system.

5. Present position (P) represents the solution to the problem, and is the usable output of the computer. Since this data is continually being revised each time the computer cycles through the program, it is stored in an easily erasable address.

If it were necessary to determine each of these quantitites, to convert it into digital form, to encode it and determine the program, and to apply these to the computer, the computer speed would be of no significant value in one-time solution. The value of computers in actual flight situations lies in the automatic and repetitive nature of the computer. Specifically, this includes the following abilities:

1. To accept the required data automatically, provided only that it be included in the program and that it be in the proper form for use by the computer.

2. To perform the programed computations with great speed.

3. To perform the same computations over and over.

4. To make corrections during each computation cycles, as the situation requires, reflecting any change in values that may have occurred since the last previous cycle.

5. To store the result of the last previous calculation for use in the next computation.

In the problem under current consideration, refer to figure 10-32. The program is built into the computer; all required data is immediately available from aircraft instruments or other computers, or it is stored in the storage unit of the computer. In connection with the solution of this particular problem, certain pertinent factors must be considered.

If the aircraft is flying at a constant velocity, the acceleration is zero, and the preliminary solution to "at/2 + b" is simply "b." The value of b from the previous cycle of computation is stored at a specified address in the memory unit; when needed, b is applied to the computer input and used in the new solution.

916

If the aircraft changes velocity, an accelerometer is used to sense and evaluate the acceleration taking place. Any increase in velocity represents a positive acceleration, whereas a decrease indicates negative acceleration. The computer must be capable of distinguishing between the two, and must be able to make the computation for either.

Multiplying the average value of acceleration during the time interval (at/2) determines the change in velocity which has occurred since the previous computation cycle. Adding this correction to the former value of b results in a new velocity, which is used in the present cycle and then stored in the memory unit at the b address for use in the next solution.

Multiplication of the new value of b by the time interval determines the change of position that has occurred since the last cycle, and indicates the correction that must be added to the last known position (P) in order to determine the new P.

P_0 represents the last known position, and is stored information. Adding the correction to the last previous result provides the computer with a new value of P which is the usable output of the computer. This information then becomes the P_0 for the next computation cycle.

If it is desired that a computer should continually calculate the course and distance from the present position to the point of origin, another section of the computer could be programed to perform the computations involved. This would require a permanently stored reference position, and additional circuitry to compare the two positions and to compute the course and distance between them. Readout of this information could be made continuous, or it could be made available upon demand. If the solution is required only upon demand, no storage is needed; if it is to be continually computed, storage should be in an easily erasable form, since it is continuously changing.

Analog to Digital Converters

During a flight, the variable quantities just mentioned probably originate in analog computers. Since a digital computer accepts only binary quantities, the analog data must be routed through a converter and changed into digital form for insertion into the computer.

Another problem involving changing quantities is the question whether the remaining fuel is sufficient to allow the aircraft to reach a given destination. Almost all factors of such a problem are variable—time, fuel, airspeed, groundspeed, drift, altitude, fuel consumption rate, etc. Analog computers determine the present value of each quantity and supply it to the converter, which then converts the data into digital form. The computer may have a program outlined by which all the variables are considered in calculations that finally result in a YES or NO answer. The YES answer might cause a green indicator to light, and NO might cause a red indication. The computer may cycle the program continually, correcting the various quantities as needed, and temporarily storing the rate of change of each quantity, as well as the value of the latest computed quantity. With this arrangement, computations based on latest available data can continue in the event of interruption of operation, and the margin of error is decreased in that event.

The limit of accuracy of a computer is the least significant digit. There is no advantage in having an analog device more accurate than the control data available to it. As an example, a servo positioned by a five-digit binary control signal can indicate no closer than 1/32 (2^5 = 32) of a revolution, or approximately 11.3° regardless of the precision of the servomotor itself. The precision of output devices should be matched to the stored data, or at least to the level of accuracy required in the output application.

Angular converter outputs may be matched in reference to a defined 0° reference, or in reference to the last previously indicated angle. Many analog to digital converters utilize a wheel, a ring, or a spiral shaft encoder which is electrically or mechanically positioned by the quantity being measured. Several general types are discussed below.

SIMPLE BINARY WHEEL.—The binary wheel is a flat disk composed of concentric circles with each ring divided into twice as many sectors as the adjoining inner ring. Thus a properly coded wheel divides a circle into sectors, with the number of rings determining the accuracy of the device. Figure 10-33 (A) shows a five-bit shaft encoder of the general type just discussed.

Instead of the concentric rings, parallel bands on the wheel perimeter could be marked, and used to perform the same function. Coding could then be based on conducting and nonconducting layers, magnetic and nonmagnetic segments, transparent and opaque segments, or

917

Figure 10-33.—A simple five-bit shaft encoder. (A) With five output requirements; (B) With a single output required.

raised and lowered segments which operate to open and close electromechanical switching devices. (See fig. 10-33 (B).)

SINGLE BRUSH SHAFT ENCODER.—A modification of the shaft encoder consists of a single brush on the shaft, making contact with multiple tabs on the perimeter of a wheel. These tabs are connected to buses in a nonrepeating binary code. Since the tabs are all on the perimeter of the wheel, only one brush is required, regardless of the number of points which are to be indicated. This results in the following three major advantages.

1. The rings need not be concentric or coplanar, but simply electrically insulated.
2. Identical printed wafers with distinctive tab codes could be stacked to form the switch.
3. A 14-digit encoder could be built using the same size case, housing, etc., as a five-bit unit.

GEAR DRIVE SHAFT ENCODER.—Most angular to linear conversion devices introduce a positional uncertainty which must be eliminated, either by limiting the permissible angle or by using two conversion units. The gear drive does not have this problem; it may be designed to represent any angle. The limits imposed are the minimum angle resolution and the maximum permissible size of the components. The minimum angular resolution is determined by the number of teeth per revolution. (See fig. 10-34.)

LINEAR POTENTIOMETER.—A potentiometer may be used with its two ends connected to fixed reference potentials. The angular position of the slider may be represented by the unloaded voltage at the slider. Any variation in the reference voltage, or any current in the sensed voltage, can introduce errors into the reading. The voltage can be used directly (analog), or it may be supplied as a scaled voltage to the converter. For digital applications, a tapped rather than continuous potentiometer may be used, with the output then encoded to binary form for input to the computer.

VOLTAGE TO NUMBER CONVERSION.—Electrical analogies (analogs) of most measurable quantities have been developed, with most instrumentation presenting its output as a scaled voltage (1 volt = 100 miles, 1 volt = 1,500 gallons, etc.). It is necessary to convert both the voltage level and the scale factor into terms usable by the computer. It is not always necessary that the scale factor be inserted, as long as the computer has it stored at a unique address.

Examples of voltage to number converters are the digital voltmeter and the self-centering potentiometer used in angle to number conversion.

VOLTAGE TO TIME TO NUMBER CONVERSION.—A coverter of the voltage to time to number type, in its simplest form, is very useful in scale systems. The converter may require clock pulses, a linear sawtooth of

Figure 10-34.—Gear drive shaft encoder.

voltage (ramp), a voltage comparison circuit, and a voltage that is to be measured.

Digital conversion is provided by starting a digital counter that has been synchronized with the sweep, and stopping it when the sweep voltage and the unknown voltage are equal. The clock pulses are counted, and the voltage change per unit time factor is applied, so that the output reading is converted into a number. There is one counter output for each sweep as long as the unknown voltage is within the calibrated range of the sawtooth.

Accuracy of this system is limited by the slope of the sawtooth, by the accuracy of the timing system, and by the precision of the voltage equality determining system. Making the same measurement concurrently (using two or more converters) and averaging the results decrease the inaccuracies of the system.

The system indicates an instantaneous value; nothing is shown concerning the behavior of the input voltage before or after its intersection with the sawtooth. The sawtooth need not be linear, provided that its voltage as a function of time is known and used in the calculation.

SELECTIVELY ADD-SUBTRACT SYSTEM.—The operating principle of this system is the same as that of an equal arm balance, where an unknown weight in one pan is balanced by selectively adding or subtracting known weights in the other pan. The limit of accuracy, disregarding friction, is ±1/2 the smallest balance weight available. Similarly, a voltage balance analog system, selectively adding or subtracting scaled resistors until balance is obtained, may be used. The advantage of this system is that the voltage may be larger or smaller than the reference voltage. A simple example is a balanced bridge with binary adjustments. The system may start from a fixed point or from the last used point, with switching automatically sequenced and controlled by the computer.

Digital to Analog Converters

It is often necessary for the digital output to be converted to analog quantities in order to actuate a servo or some other device of an analog nature. Again, a converter is required; but in this case, it must be a digital to analog converter.

Practically any encoder (analog to digital converter) can be used as a decoder (digital to analog converter), either directly or in combination with a null-seeking driver. Frequently the only modification required is reversing the input and output functions of the device.

Readout Devices and Methods

Symbolic displays are generally employed for immediate use. The display system (matrix) may be formed by an array of individual lights; at may be based on variations of intensity or color on a CRT; or it may represent the locus of points on an X-Y plotter or on

a DRT plotter table. Computer output voltage levels and data rates can be adapted to produce any of these displays. The specific type selected will depend primarily on the application.

Timing and retentivity (or recording) may be selected to provide a display similar to that of an oscilloscope, of a radar indicator, or of a television set. The data can be arranged in alphanumeric, graphic, or photographic form. Multiple displays, using combinations of several individual display systems, are used in most airborne and military computers, both digital and analog. Figure 10-35 illustrates several common readout devices.

LIGHTS. —Each individual light may be considered as the equivalent of a binary stage: ON—true or one; OFF—false or zero. Lights are used to display such discrete data as fail-safe, on-off, and warning. They may be used in groups and in conjunction with ring counters to form binary to decimal conversion displays. Each individual light is sequenced and illuminates the appropriate digit when switched by the counters. (See fig. 10-35 (A).)

MULTIFILAMENT LIGHTS. —These lights may display numbers, letters, symbols, or combinations of these. Filaments may "edge light" lucite cards to illuminate engraved symbols, or may actually be shaped in the form of the symbol and glow when switched on. (Note fig. 10-35 (B) and (C).)

Lights require appreciable current—greater than that which is normally available directly from the computing circuits. Therefore, a buffer or amplifier stage is usually required to furnish the additional current. Since a single display illuminates multiple symbols and requires at least one terminal for each, it may require its own counter circuits to convert from binary code to the display code, or it may share a common converter with several other circuits. On the other hand, the individual filaments may be prewired to a printed circuit board, and the appropriate display selected and switches by computer circuitry.

The value or quantity being measured may be represented by a positioned display of multiple filament lights. The digital voltmeter is a fairly common example of the use of these lights.

WHEEL DISPLAYS. —Any one of the angle to number converters previously described can be connected as an output device, either to furnish an angle signal or display (pointer or servo signal) or to mechanically position a particular symbol on a wheel display. The symbol to be displayed can be any arbitrary number, letter, word, or other symbol selected by the designer.

The wheel can be positioned by a servomotor, by a step counting switch, by a digital to analog converter coupled with a motor, etc. The only limitation on the positioning system is that it must be able to drive the wheel until the correct symbol is displayed.

The display may be generated by wheels geared together in a fixed ratio (as in an odometer) or with each wheel individually driven and positioned. A disadvantage of the second system is the increased frontal area required to accomodate the drive mechanisms. The number of symbols to be displayed is limited by the size of the wheel and by the number of discrete positions that can be selected. (See fig. 10-35 (D) and (E).)

TAPE DISPLAYS. —Rather than increasing the size of the wheel to increase positional accuracy and to increase the number of symbols that can be displayed, tape displays are frequently used. The small wheel simply acts as an idler wheel for a tape bearing a large group of symbols. This system has several advantages, but the primary advantage is that it provides a clearly legible (precise) display in a minimum of space.

Many "games" can be played with the tape system to increase packing density. The digits of several tapes may be alined and projected. The depths of the tapes can be staggered, making it possible to package the drive mechanisms in line with the tapes. The tape can be coded and may actually carry the control wiring for its own positional drive motor, simplifying external wiring.

The tape (if of a sufficient free length-to-width ratio) may be formed into a "Möbius band," permitting doubling the number of symbols on a band of given length and/or permitting staggering the symbols so they can be transilluminated (projected). (See fig. 10-35 (F).)

PLOTTERS. —Digital computers frequently use plotters to represent two properties of a variable: latitude and longitude, altitude and bearing, amplitude and time, etc. Most digital plotters are simply plotters which already exist for analog systems, with the computer merely furnishing signals through digital to analog converters as the input signals.

The plotter may be either of the recording or the nonrecording type. The digital data

920

Figure 10-35.—Readout display matrices. (A) Positional illuminated display; (B) 5 x 7 alphanumeric display; (C) 3 x 6 dot display; (D) side display; (E) perimeter display; (F) tape display; (G) Cartesian coordinates display.

displayed (plotted) are a series of discrete values. If the points are readily distinguishable from each other, more than one curve may be plotted at one time. The plot is affected by the number and type of recording heads, the speed of response, and the rate of travel. Since it requires no motion, the nonrecording CRT is one of the fastest plotting systems, and is one of the most common used.

Another common system, the moving ribbon recording oscillograph, uses pencil or pen on regular or graph paper, pressure-sensitive paper, electrosensitive paper, Xerography, photography, or waxed paper. The motion of the paper generates one dimension (generally the time, control, or X coordinate), while the lateral motion of the recording device generates the second dimension.

In other systems the recording device is moved in both the X and the Y coordinates over a stationary surface. This is the principle of the oscilloscope and the DRT table. A direct digital control divides the X-Y plane into discrete points, determined by the matrix. A buffer stage may be necessary between the measured voltage and the coverter, in order to insure sufficient power to drive the mechanical device. The buffer may be gated to accept a signal only upon command from the computer, or it may be gated continuously.

Selection of the type plotter for use is frequently made on the basis of the input signal. Slowly varying signals may use a mechanical device, while rapidly varying signals may require a more rapid system. Figure 10-35 (G) illustrates a display of Cartesian coordinates by means of individual lights.

OPERATIONAL CIRCUITS.—Another set of outputs commonly used in military computers are the operational outputs, actual command and control signals to other systems or subsystems. They may be in any of the forms previously discussed.

ANALOG COMPUTER AN/ASA-47

The Doppler/Air Mass Navigational Computer, AN/ASA-47, is an electromechanical analog computer used in the P-3A aircraft as a backup for the primary navigation system. It provides continuously updated electrical outputs representing N-S and E-W groundspeeds and distances traveled. It computes the N-S and E-W groundspeed components either by converting the on-heading and cross-heading Doppler inputs, or by summing the true airspeed and wind. Groundspeed components are provided to the AN/ASN-12 continuously to correct for the effects of acceleration and velocity on the platform. In addition, when the NAV SYSTEM selector switch (fig. 10-36) is in either the AN/LN-2C or the AM/AHRS position, the ASA-47 furnishes N-S and E-W velocity components to the AN/ASA-16.

The Doppler/Air Mass Navigational Computer consists of a computer and control indicator (figs. 10-36 and 10-37) and a mount. A simplified block diagram is provided in figure 10-38. The equipment supplies the following:

1. N-S and E-W distance-traveled outputs to using equipment by intergrating either Doppler radar or true airspeed-plus-wind velocities.
2. N-S and E-W aircraft groundspeed components to AN/ASA-16 for aircraft course computation and to the ID system for vehicle velocity corrections.
3. True heading output by adding magnetic heading from the AHRS to automatically computed or manually set variation from the inertial Doppler.
4. True bearing outputs by adding magnetic variation to the magnetic bearings received from the AN/AQA-1.
5. A navigation system mode select switch on the control panel for selection of the tactical navigation system to be used.
6. Drift correction to the AN/ASA-16.

FUNCTIONAL DESCRIPTION

The computer box of this system is located on a shock mount above the navigator's station in the tactical area, and the control indicator is located in a rack above, and outboard of, the PT-396 Plotter at the navigator's station. The system may be operated in either DOPPLER or AIR MASS modes. With the mode switch in DOPPLER position, the computer will be automatically switched to the air mass mode of operation if any of the following three conditions exists:

1. Doppler radar goes into memory operation.
2. Aircraft bank angle is greater than 30°.
3. AN/ASA-16 initiates a bootstrapping operation.

In a bootstrapping operation, the AN/ASA-16 computes an incremental velocity that is needed in order to compensate the N-S and E-W distance-traveled outputs for sonobuoy drift, navigation system errors, etc. The AN/ASA-16 correction velocities are summed with true airspeed and wind at the input of the integators. Bootstrapping is done in the air mass mode of operation as Doppler velocity signals are subject to errors and memory operation during maneuvers. Provisions have been made to allow bootstrapping, in Doppler mode if future improvements result in better Doppler information during maneuvers.

In the Doppler mode of operation, V_h and V_d from the Doppler radar are resolved with true heading input to obtain N-S and E-W aircraft velocity components for the inertial navigator, groundspeed and drift angle indicator, and AN/ASA-16. Resolved true airspeed is compared with resolved Doppler velocities to

Figure 10-36. —ID-995/ASA-47 position indicator.

obtain N-S and E-W wind as an electrical output to the AN/ASA-16 and as a visual readout on the control indicator. Wind may be read out in either Cartesian or polar coordinates on the display. N-S and E-W components of Doppler velocities are integrated to obtain distance traveled as synchro outputs to the PT-396 and PT-434 Plotters, ID-888/U LAT-LON Indicator, AN/APA-125 Radar Indicator, and AN/ASA-16 Tactical Display.

In the air mass mode of operation, resolved true airspeed is added to last computed or manually set wind to obtain velocity outputs for the inertial navigator, GSDA, and AN/ASA-16, and integrated to obtain distance-traveled output for using equipment listed above. Manually set or last computed wind components are also supplied to the AN/ASA-16.

Integrataion in air mass mode does not occur unless true airspeed is greater than 100 knots. This feature is necessary to prevent integration prior to takeoff because the TAS Computer has a minimum output of 70 knots. A ground signal is supplied to the inertial navigator whenever true airspeed is greater than 100 knots to indicate that the DOP/AM computer is functioning and that the inertial

Figure 10-37.—CP-640/ASA-47 navigational computer.

navigator can rely on groundspeed being supplied to it. Magnetic variation is supplied to the equipment by the inertial navigator to allow conversion of magnetic heading from the AHRS to true heading for system use in the AM/AHRS Navigation mode. The DOP/AM Computer also converts two sonobuoy magnetic bearing signals from the AN/AQA-1 Indicator Group to two true bearing signals which are displayed on the AN/ASA-16 Tactical Display.

Position Indicator

The Position Indicator, ID-995/ASA-47 (fig. 10-36) sometimes called the control indicator, contains all normal operating controls for the computer, the windspeed indicator, and the wind computation servos. The unit consists of various assemblies mounted on a frame. The indicator assembly is at the front; electrical components, including the power transformer, are at the rear. The power transformer is enclosed in a mu-metal shield. At the top are four plug-in amplifiers which are accessible when the cover is removed. These are sealed units not repairable in the field. To prevent improper installation, each type of amplifier throughout the AN/ASA-47 is keyed by the arrangement of its connectors and mounting pins. All other electrical components are mounted either directly to the frame or on component boards which are then secured to the frame. All connections to the position indicator are made through two receptacles mounted on the lower rear of the unit. A door on the top of the unit can be opened to make adjustment.

The front panel controls and indicators include the ON-OFF switch, the NAV SYSTEM selector switch, the DOP-A/M mode switch, the 50-150 knot wind scale switch, the N-S and E-W manual wind input knobs, the NO GO and DOP OFF indicator lamps, and the wind indicator assembly. The wind indicator assembly consists of a clear plastic dial, a wind heading index, and an N-S and an E-W windspeed indicator or cursor. The dial has a 50-knot and a 150-knot scale engraved on it and can be rotated by two plastic knobs mounted directly on the dial face. The wind heading index, around the wind indicator dial, provides compass wind heading in 1° increments. The N-S and E-W wind cursors are engraved on plastic curtains which are visible through the clear plastic dial.

Navigational Computer

The Navigational Computer, CP-640-ASA-47 (fig. 10-37), which is mounted on the resilient mount, contains all of the required computing elements except for the two wind servos. On the front panel of the navigational computer are three active fuse holders and two spares; an elapsed time meter, M1; and a test receptacle. Two hinged doors on the front panel cover screwdriver calibration controls and a test input panel. The N-S and E-W integrator dials, which are part of the corresponding integrator modules mounted inside the navigational computer, can be viewed through windows on the test input door. The true airspeed dial, which is mounted on the true airspeed module, is visible on the left side of the computer.

Mounted on the left side of the main frame of the navigational computer are five modules: Ground Speed Module 2A2, True Airspeed Module 2A3, True-Heading Module 2A4, Variation Module 2A5, and N-S Integrator Module 2A6. Also mounted on the left side of the unit at the rear bottom are the Doppler reference transformer and the N-S groundspeed output transformer. Two relay sockets, into which are plugged crystal-case relays, are mounted on the left side of the frame. Five electrical connectors are located on the rear of the frame.

924

Figure 10-38.—Doppler/Air Mass Navigation System block diagram.

The E-W Integrator Module 2A7 and the crystal-case plug-in relays are mounted on the right side of the frame. Signal reference transformer, E-W groundspeed output transformer, and linear transformers are also located here.

THEORY OF OPERATION

The Doppler/Air Navigation Computer, AN/ASA-47, performs several functions in the operation of the P-3A navigation system. Figure 10-39 shows the computer in a simplified block diagram. The AN/ASA-47 computes groundspeed and ground track in the N-S and E-W components. The wind velocity is computed in the Doppler mode of operation; but in the air mass mode, the value last computed is remembered or wind is manually inserted. The computer also adds variation corrections to magnetic heading and magnetic bearing to provide true bearings. Outputs of true heading and true bearing; the components of groundspeed, ground track, and wind velocities; and electrical ground signal when true airspeed exceeds 100 knots, are provided to other elements of the navigation system.

As shown in figure 10-39, the computer has seven functional modules. Six of these modules, True Airspeed, True Heading, Groundspeed, N-S Integrator, E-W Integrator, and Magnetic Variation are in the computer unit. The seventh module, Wind Solution, is an integral part of the indicator unit.

Doppler Mode

In the Doppler mode of operation, the computer receives inputs of true airspeed (TAS), V_t; true heading, H_t; on-heading groundspeed, V_h; and cross-heading groundspeed (drift), V_d. The Doppler mode of operation is also known as the groundspeed mode, since groundspeed is received directly by the computer. A prime function in this mode is to compute the rectangular components of windspeed.

925 ase

Figure 10-39.—Doppler/Air Navigational Computer simplified block diagram.

Windspeed is the vectorial difference between true air velocity and ground velocity; that is, windspeed is the speed of the aircraft with respect to the ground because of the effects of the wind. If the direction and magnitude of both the airspeed and groundspeed are known, the corresponding value of windspeed can be determined. In the AN/ASA-47, the windspeed is found in terms of its rectangular, or N-S and E-W components.

TAS is received as a synchro signal by the true airspeed module, which converts it into a form more usable in the computer. This value is then fed to the true heading module, which also receives the true heading, H_t, either from the AN/ASN-42 or from the output of the variation module of the AN/ASA-47, depending on the position of the NAV SYS mode switch. TAS is resolved into its N-S and E-W components by multiplying V_t by the cosine and sine, respectively, of the true heading angle, H_t as shown in figure 10-40.

On-heading groundspeed, V_h, and cross-heading groundspeed, V_d, are received by the groundspeed module as separate 400-cycle

Figure 10-40.—Resolution of airspeed, V_t, into rectangular coordinates.

input signals from the Doppler Radar AN/APN-122. Each is converted into the proper form and fed to the true heading module. In this module, each value is separately resolved into its N-S and E-W components, as shown in figure 10-41; and the corresponding rectangular coordinates are algebraically summed to obtain the N-S and E-W components of groundspeed. The N-S airspeed is algebraically added to the N-S groundspeed to find the N-S windspeed. The two wind components are transmitted as 400-cycle signals to the wind solution module in the position indicator unit and to the other elements of the navigational system.

The N-S and E-W components of groundspeed are applied as 400-cycle input signals to the two integrator modules. The N-S and E-W integrator modules are identical. Each integrator receives its corresponding groundspeed signal and a 400-cycle velocity correction signal. When a velocity correction command signal is received from the AN/ASA-16, computation automatically transfer to the air mass mode. The velocity correction signal is summed with the groundspeed signal to produce a correct N-S or E-W groundspeed signal (depending upon the integrator module). The groundspeed signal is applied to other elements of the navigational system as a 400-cycle signal voltage. The signal voltage is also integrated to find the distance traveled over the ground, which represents the change in position in a N-S or E-W direction.

Figure 10-41.—Resolution of groundspeed, V_g, into rectangular coordinates.

The distance traveled outputs are provided as synchro signals.

The wind solution module contains servos which utilize the two windspeed component signals for mechanically positioning the indicator unit display crosshairs. By rotating the scale to intersect the point of intersection of the crosshairs, the navigator can read the windspeed and direction.

The magnetic variation modules receives a magnetic variation signal from the AN/ASM-42 (ID), two separate magnetic bearing signals from the AN/AQA-1, and a magnetic heading signal from the AN/ASN-37 (AHRS). These are all synchro signals. A servo in the module provides a shaft position proportional to magnetic variation. Each synchro is positioned by the variation correction shaft to provide two separate true bearing signals and a true heading signal. These outputs are all in synchro signal form.

The true heading module also provides a true heading synchro signal to other elements of the navigational system. The true airspeed module provides a signal (contact closure) to the rest of the navigational system when the true airspeed exceeds 100 knots.

Air Mass Mode

In the air mass mode of operation, which is also known as the airspeed-wind mode, groundspeed is not known and must be calculated before the N-S and E-W components of distance traveled can be found. However, since windspeed, obtained from another source or estimated, can be inserted manually into the computer and true airspeed is known, the computer can calculate groundspeed. Except for the groundspeed, wind solution, and true heading modules, the functional modules in the computer operate in the same manner in the air mass mode as they do in the Doppler mode.

The groundspeed module does not have any effect on the air mass mode, groundspeed, and distance traveled computations. The wind solution module acts as a signal converter, providing 400-cycle N-S and E-W speed signals proportional to the manual input values to the true heading module. The windspeed signals are also transmitted to other elements of the navigational system.

927

The operation of the true heading module is essentially the same in the air mass mode as it is in the Doppler mode, except that the equations being solved are slightly different in form. In the Doppler mode, the N-S and E-W groundspeed components are found by resolving the on-heading and cross-heading groundspeed about the heading angle. In the air mass mode, the groundspeed is found by adding the respective components of windspeed and air speed. (See fig. 10-42.) In the Doppler mode, the windspeed components are found by algebraic addition of airspeed and groundspeed. In the air mass mode, windspeed is a preset input.

Automatic Mode Switching

The AN/ASA-47 system automatically switches to the air mass mode of operation when the Doppler information becomes unreliable. A signal from the AN/APN-122 Doppler causes the computer to operate with the last computed and remembered windspeed components as input values. When the Doppler information again becomes reliable, the computer reverts to the Doppler mode, again computing the wind solutions.

As mentioned previously, a similar action takes place when a velocity correction command is received. In this case, the AN/ASA-16 supplies a signal which switches the computer to air mass mode. The windspeed components become remembered values, and the groundspeed velocity correction is applied. When the velocity correction command is removed, the computer reverts to normal Doppler mode operation. Normal control of mode of operation is maintained by a front panel switch on the computer. Either a Doppler unreliable or a velocity correction relay signal overrides the Doppler mode switch position, causing the system to compute in the air mass mode.

Figure 10-42.—Solution of windspeed by algebraic addition.

ALINEMENT, CALIBRATION, AND MAINTENANCE

A complete set of schematic diagrams, wiring diagrams, alinement procedures, list of test equipment required, and other maintenance information can be found in the appropriate service manuals.

The Doppler/Air Mass Navigation Computer must be kept in close alinement to operate properly as part of the P-3A navigational computer system. The alinement should be checked after 20 operational hours; if it is found to be out of tolerance, it should be corrected. The alinement procedure to be used for checking and resetting is given in the service instruction manual.

CHAPTER 11

ANTENNAS AND PROPAGATION

After an RF signal has been generated in the transmitter, there must be a means of radiating the RF energy into space, and a means by which this signal may be intercepted (picked up) for the receiver. The device which fulfills both of these requirements is the ANTENNA. The major purpose of a transmitting antenna is to convert the transmitter's RF power into radiated energy as efficiently as possible; the major purpose of a receiving antenna is to absorb as much of this radiated energy as possible.

The process by which the RF electrical energy is converted into electromagnetic waves and radiated into space is called PROPAGATION. Certain basic concepts of propagation and antennas are included in Basic Electronics, NavPers 10087-B. These basic concepts should be thoroughly reviewed at this time to insure a full understanding of the fundamentals of propagation, prior to completing the work on this chapter.

This chapter is a continuation of the material covered in Basic Electronics, and in addition covers sections on antenna arrays and typical airborne antennas. The aim of this chapter is to more fully acquiant the AT with the mechanics of propagation, the results of irregularities in the atmosphere, the consideration required in the selection of the proper frequency for specific purposes, and the operational characteristics of the various types of antennas and arrays.

In the study of this chapter, it should be kept in mind that the subject matter field is broad and no attempt at complete coverage is made. Rather, only such background information as will be of help to the AT is included. In many instances, the AT will have the assistance of field engineers, or will at least have specific instructions on how to perform many jobs. He therefore will, in practice, need much of the information contained in this chapter only as a necessary background.

When considering the energy radiated from an antenna, an important concept is the DIRECTIVITY of the antenna. The directivity of an antenna is a measure of its ability to radiate energy in the desired direction (or directions) and to suppress the radiation in other directions. The same is true of a receiving antenna; in this case, signals from the favored direction (or directions) are received more easily than those from other directions.

The RADIATION PATTERN, which is a good indication of the directivity of an antenna or antenna array, is usually plotted on polar graph paper. It should be emphasized that when polar coordinates are used, the resulting curve is NOT an actual picture or outline of the energy radiated by the antenna. It is rather an indication of the relative amount of energy delivered to points on an imaginary circle a certain distance from the antenna, which is usually located at the center. The points where the measurements are taken are usually spaced 10° or more apart. Thus, the polar plot is a good picture in two dimensions of how directive the antenna is. (See fig. 11-1 (A).)

It should be emphasized also that the pattern is three dimensional, although the plot is commonly given only in the horizontal or vertical plane. The rounded projections of the polar pattern are called LOBES and the indented portions, representing minimum energy pickup in the test antenna, are called NULLS.

REVIEW OF PROPAGATION PRINCIPLES

From your study of Basic Electronics, NavPers 10087-B, you will recall that a radio-frequency current flowing in a wire of a finite length can produce electromagnetic fields that may become disengaged from the wire and set free in space. The principles of the radiation of electromagnetic energy are based on the laws that a moving electric field creates

Figure 11-1.—Antenna radiation. (A) Radiation pattern; (B) wavefronts.

a magnetic field, and (conversely) a moving magnetic field creates an electric field. The created field (either electric or magnetic) at any instant is in phase in time with its parent field, but is perpendicular to it in space. These laws hold true whether or not a conductor is present.

ELECTROMAGNETIC FIELDS IN SPACE

The E- and H-fields are mutually perpendicular to each other and to the direction of travel. These fields, traveling through space together, form a radio wave. The frequency of the radio wave is the same as the frequency of the RF current which produced it. Radio waves are radiated into space at the speed of light, 186,000 miles (or 300,000,000 meters) per second. This velocity is constant, regardless of frequency. Because of this constant velocity, it is possible to establish the relationship between the frequency and the wavelength. This relationship is expressed as

$$\lambda = \frac{300}{f} \text{ or } f = \frac{300}{\lambda}$$

where λ is the wavelength in meters, f is the frequency in megacycle, and 300 is the velocity of travel in millions of meters per second.

Wavefronts and Polarization

Energy from the transmitting antenna moves outward in ever-expanding spheres. A small portion of one of these spheres is called a WAVEFRONT. As indicated in figure 11-1 (B), the H-lines are perpendicular to the E-lines, and both are perpendicular to the direction of propagation. A right-hand rule that ties these three quantities together is given in Basic Electronics, NavPers 10087-B.

HORIZONTAL POLARIZATION means that the electric lines are horizontal with respect to the earth, and VERTICAL POLARIZATION means that the electric lines are vertical with respect to the earth. The choice of the electric field as a reference field results from the practice of measuring radio wave intensity in terms of electric field intensity (for example, microvolts per meter).

Reflection, Refraction, and Diffraction

When one is considering the movement of electromagnetic fields through space, it is very important to understand clearly what is meant by reflection, refraction, and diffraction. Because radio waves of short wavelengths act somewhat like light waves (both of which are electromagnetic radiations), it is well to consider these effects from the point of view of light waves, which may be more readily observed.

A basic coverage of the reflection and refraction of light is to be found in chapter 4 of Aviation Electronics Technician 3 & 2, NavPers 10317-C. A review of these principles at this time will be of great help in understanding the action of radio waves in space.

Reflection takes place only when the reflecting surface is large compared to one-half the wavelength of the incident wave, and smooth for an appreciable portion of one-half wavelength. Under these circumstances, the angle of incidence is equal to the angle of reflection. When these conditions are not met, scattering will occur. Scattering is a common occurrence. As a matter of fact, FORWARD SCATTER of radio waves in the troposphere and ionosphere (because of irregularities in density) is an important method of radio wave propagation.

The INDEX OF REFRACTION is a term used to describe how much bending will take place as electromagnetic waves pass through a given substance. The higher the index of refraction, the more the bending. The index of refraction is the ratio of the velocity of light waves in a vacuum to the velocity of light in the substance being considered.

In the case of radio waves being refracted in the ionosphere, the path is gradually curved because there is no sharp point of transition between layers of different densities. Those rays that make a large angle with respect to the horizontal along the earth may be refracted a small amount and pass on through the ionosphere to outer space; those that make a smaller angle will travel a greater distance in the ionosphere and may be bent to such an extent that they will return to earth. The net result is as if the wave had been REFLECTED back to earth. A simplified illustration of ionospheric refraction is given in figure 11-2. A certain amount of refraction also takes place in the troposphere (below the ionosphere) because of the proximity of warm and cold air masses.

Diffraction of light occurs when a beam of light passes over the edge of an opaque object. The energy is bent, or diffracted, around the edge of the object, as indicated in figure 11-3. Instead of a sharp outline being formed, the shadow will be blurred because of the bending of the light around the object. Red light (long wavelength) is bent into the shadow more than violet (short wavelength).

Low frequency radio waves bend around natural obstructions, such as mountains, in much the same way that light does. At the higher frequencies, the bending is much less apparent.

Although these effects (reflection, refraction, and diffraction) have been listed separately, it is not uncommon for them to occur simultaneously. In addition, there are other factors, such as energy loss due to absorption, changes in polarization, and reinforcement or cancellation due to variations in signal path lengths. Therefore, it is frequently difficult to discover exactly what has happened to the radio wave during its passage from the transmitter to the receiver.

Figure 11-2. —Refraction in ionosphere.

Forward Scatter of Radio Waves

Much research is being conducted at present to determine the practical use to which the phenomenon of FORWARD SCATTER may be put.

Forward scatter is believed to be due to small variations in the composition of the atmosphere. This lack of homogeneity may be created by such irregularities as the ionization left by meteor trails, ionospheric winds, auroral effects, tropospheric turbulence, variation of the refractive index, etc. The net effect is a scattering of radio waves in all direction, especially in the forward direction of travel. By the use of powerful transmitters, highly directional antennas, and light-gain receivers, scatter signals from the troposphere may be received up to 600 miles and scatter signals from the ionosphere may be received at distances of 600 to 1,200 miles. For tropospheric scatter, frequencies between

Figure 11-3. —Diffraction.

100 mc and 10,000 mc have been used; for ionospheric scatter, frequencies between 25 mc and 60 mc have been used.

Although much work remains to be done in this field, it seems probable that VHF frequencies will become increasingly important in long range communications. For ranges up to 600 miles where tropospheric scatter is effective, the useful frequency range probably will be greatly extended.

IONOSPHERIC VARIATIONS

Variations in the ionosphere greatly affect the propagation of certain radio waves. It is therefore necessary to include a brief treatment of the variations that take place in the ionosphere. Although a degree of irregularity is characteristic of all ionospheric variations, nevertheless it is convenient to subdivide them into both irregular and regular variations.

Irregular variations cannot be accurately predicted in advance; regular variations follow a general pattern, and therefore may be predicted with some degree of accuracy.

Certain basic information on the ionosphere is given in Basic Electronics, NavPers 10087-B and should be reviewed at this point.

Irregular Ionospheric Variations

SUDDEN IONOSPHERIC DISTURBANCE.—This type of disturbance in the ionosphere is caused by radiation from solar flares that produce intense ionization in all layer of the ionosphere in daylight areas.

Frequencies above 1 or 2 mc (depending on the intensity of ionization) are largely absorbed in the heavily ionized D layer. Higher frequencies may be used for short distance communications, and lower frequencies (which do not penetrate the D layer) may be used for long distance communications.

IONOSPHERIC STORMS.—These magnetic disturbances occur about 18 hours after solar flares. The upper ionosphere expands and becomes diffused, the effects being more severe near the poles and less severe near the Equator.

Ionospheric storms may last from a few minutes to several hours; the intensity then diminishes, and the effects disappear in a few days. During the peak of the storm and for a period thereafter it may be necessary to use lower than normal frequencies, especially in high latitudes.

SPORADIC DISTURBANCE IN THE E LAYER — Frequently, "clouds" of abnormal ionization occur at the approximate altitude of the E layer. The occurrence is spotty both in time and place. This results in excellent reception within the normal skip distance, and occasionally long distance communication may be obtained above 60 mc The frequency may have to be lowered to maintain communications over short skip distances.

SCATTERED IRREGULARITIES IN THE IONOSPHERE.— Scattered irregularities in ion density may cause scattered reflections and

resultant signal fading. This is due to varying phase relations resulting from variation in signal path lengths. It is a situation that must be tolerated.

EFFECT OF METEORITE TRAILS. — Large numbers of meteorites enter the upper atmosphere during the course of a day. A portion of the energy released as these particles are slowed down is utilized in ionizing the atmosphere. The volume of the atmosphere ionized by one of these particles is very large, considering the size of the particle. It may be several feet in diameter and perhaps a mile or more in length. Even though recombination of the ions occurs very rapidly, nevertheless ionization often lasts long enough to cause radio stations to be heard that would not normally come through.

Research is currently being done in this field, and perhaps the effect of meteorite trails on propagation may, in time, be used to great advantage.

Regular Ionospheric Variations

ELEVEN-YEAR SUNSPOT CYCLE. —Periods of maximum sunspot activity occur 11 years apart. For example, the last period of maximum activity was during 1958-1959; the next one will be 1969-1970.

During these periods, the F1 and F2 layers, especially, increase in density and height. In general, higher operating frequencies are necessary for long distance communications.

SEASONAL VARIATIONS. —During the summer months the height of the F2 layer is increased, and during the winter months it is decreased. During the winter months the ionization density rises earlier in the day, and reaches a higher value than in the summer months; the predawn ion density reaches a lower value. The F1, E, and D layers reach lower maximum densities in winter.

Medium high frequencies are used for long distance, winter communication; the lower high frequencies are used for medium distance communication.

TWENTY-SEVEN-DAY SUNSPOT VARIATIONS. —These disturbances accompany sunspot activity that occurs every 27 days. This interval is the time required for the sun to complete one revolution about its axis. The effect on radio transmission is essentially the same as that of sudden ionospheric disturbances.

DIURNAL (DAILY) VARIATIONS. — During the daylight hours the density of the F layers increases; the thickness of these layers also increases during this time. During the course of the day, the F layer splits into the F1 and F2 layers. The ion density of the F1 layer varies with the vertical angle of the sun, and the ion density of the F2 layer increases to a peak somewhat later in the day.

The ion density of the E layer varies with the vertical angle of the sun, and the height remains approximately constant; the E layer is much weaker at night.

The D layer appears after dawn, and the ion density varies with the vertical angle of the sun; it dissapears at night. The D layer is located between 40 and 50 miles above the earth's surface.

CHOOSING THE PROPER FREQUENCY

The frequencies with which the AT normally works range from about 15 cps or less up to about 300 gigacycles (300,000,000,000 cps) or higher. For convenience, these frequencies are divided into BANDS. Audiofrequencies extend from about 15 cps to about 15,000 cps, and embrace those frequencies that are audible to the normal human ear. These frequencies are not normally connected with radiation and antennas.

The classifications of the various bands in the RF spectrum are shown in table 11-1.

The frequencies included in the UHF and the microwave ranges are usually considered as 225 mc through 30 gigacycles, indicating that there are some areas of overlapping in this type breakdown. In order to prevent confusion and to further break these important bands into smaller divisions, the system of classification shown in table 11-2 has been adopted.

Figure 11-4 shows the frequency distribution in the RF spectrum. The figure also indicates the uses to which portions of the RF spectrum are put. For example, the radar bands extend from the VHF to the EHF band; the commercial television channels cover portions of the VHF and UHF bands; and communications make use of all of the bands except the EHF. Newer developments indicate that even the EHF band will be used in the near future. The approximate distances covered are also indicated, as well as the types of transmission lines commonly used and the types of interference commonly experienced.

Table 11-1. —Radiofrequency classifications.

Band	Frequency spectrum (kc)	Wavelength in meters
VLF (Very Low)	10 - 30	30,000 - 10,000
LF (Low)	30 - 300	10,000 - 1,000
MF (Medium)	300 - 3,000	1,000 - 100
HF (High)	3,000 - 30,000	100 - 10
VHF (Very High)	30,000 - 300,000	10 - 1
UHF (Ultrahigh)	300,000 - 3,000,000	1 - 0.1
SHF (Superhigh)	3,000,000 - 30,000,000	0.1 - 0.01
EHF (Extremely High)	30,000,000 - 300,000,000	0.01 - 0.001

Sky-Wave Propagation Versus Frequency

As has been stated, the higher the frequency of transmission the lower must be the angle of radiation for effective transmission. This results from the fact that high frequency radiation passes through into space and is effectively lost when the angle of radiation is high. Low frequency radiation may be returned to earth even if it is radiated vertically upward. (As a matter of fact, the effective height of the ionosphere can be determined by directing low frequency pulses vertically upward toward the ionosphere and measuring the time lapse between the transmitted pulse and the echo. Knowing the velocity of radio waves, it is relatively easy to compute the effective distance.)

If the frequency is increased while the height measurements are made, it will be found that above a certain frequency (the CRITICAL FREQUENCY) echoes are not returned to earth. However, if the radiation angle is reduced sufficiently, echoes will be returned to earth at some distance from the antenna. The distance depends on the height and density of the ionosphere.

For the E layer, the critical frequency is from 1 to 4 mc, depending on the ion density of the E layer. For the F2 layer (daytime), the critical frequency is approximately 2.5 mc, and for the F layer (night), it is approximately 12.5 mc.

MAXIMUM USABLE FREQUENCY. — Because less energy is absorbed out of high frequency radiation during transmission, it is desirable to know the maximum usable frequency (MUF) that may be employed in transmission. Higher frequencies will pass through the ionosphere and will be lost to the communication circuit, and lower frequencies will be seriously attenuated in the ionosphere.

Data on the maximum usable frequency is collected by the National Bureau of Standards and is made available to the Navy in the publication, Basic Radio Propagation Predictions.

LOWEST USEFUL FREQUENCY. — As the radiated frequency is reduced below the MUF,

934

Figure 11-4.—RF spectrum.

more and more energy is absorbed from the wave and is lost, as far as communication is concerned. This absorption occurs principally in the D and E layers, which are maximum during the daylight hours, especially for frequencies between 500 kc and 2,000 kc. At the lowest useful frequency (LUF) the signal strength reaching the receiver barely overrides the background noise. Frequencies below this cannot override the noise and therefore serve no useful purpose.

OPTIMUM WORKING FREQUENCY. — Because both the height and the density of the various layers of the ionosphere may change from hour to hour, it is not possible to predict the exact MUF for each hour. Predictions are based on averages made over a long period of time. Therefore, it is necessary to choose an operating frequency that will not shift above the MUF when sudden changes in ionosphere occur. This frequency (15 percent below the MUF for F2 transmission) is called the optimum working frequency. When the lowest usable frequency is only slightly below the maximum usable frequency, the 15 percent figure may not apply.

EFFECT OF ANTENNA SITE

Should you be required to set up a VHF or UHF communication station at a forward base or at some training location, careful attention should be given to antenna location. In general, the following rules apply:

1. Locate the antenna as high from the ground as is practical.
2. In VHF installations locate away from manmade noises.
3. Locate on the highest ground in the area.
4. If possible, choose a site that is flat (that is, no hills or forests).

However, as with most general rules, there are exceptions. One factor that should be taken into serious consideration in the selection of the antenna site is the possibility of using the phenomenon known as OBSTACLE GAIN. Experiments with long range VHF transmission in mountainous regions have demonstrated the possibility of using knife edge obstacles as a means for increasing the received signal energy. Indications are that the disadvantages normally attributed to the transmission of very high frequencies (30 to 100 mc) among high mountain ridges can actually become powerful aids for reducing both transmission loss and tropospheric fading. The results of these obstacle gain experiments may have a deciding influence on the choice of sites for transmitting and for booster station installations. For example, it may prove more

advantageous to locate stations at lower elevations a short distance away from the mountains, rather than on the foothills right up against very high mountains.

The theory upon which obstacle gain transmission is based states that the transmission of VHF over a knife edge type obstacle should be considered as a combination of reflection, diffraction, and atmospheric refraction. Thus, if a transmitter and receiver are separated by a mountain, the radio waves would be received by means of the following mechanisms:

1. Diffraction at the top of the obstacle.
2. Reflection from the ground between the transmitter and the obstacle, and then diffraction over the obstacle.
3. Diffraction over the obstacle and reflection from the ground between the obstacle and the receiver.
4. A combination of the two ground reflections, with diffraction over the obstacle.

One requirement for use of the obstacle gain method for increasing signal strength is that the height of the obstruction must be greater than that of the common horizon.

Radio waves transmitted over the theoretically smooth, spherical earth are considered to arrive at points within the radio horizon by virtue of a normal diffraction process, and by scattering from the turbulet atmosphere. The turbulence, which is greatest near the earth's surface and decreases with increasing height into the upper atmosphere, is also considered responsible for the relatively weak and fading signals normally observed at distances well beyond the horizon. The obstacle gains associated with a properly situated knife edge ridge have been found to be large enough to reduce the transmission loss accompanying the reception of these signals beyond the horizon, thereby effectively eliminating the fading associated with the atmospheric scattering process.

A mountainous obstacle extending well above both the transmitting and receiving antennas requires the radio waves to pass through the most turbulent and disturbing regions of the atmosphere at relatively high grazing angles. With these large grazing angles, the amount of energy received from the highly turbulent regions in the screened lower portion of the atmosphere is effectively eliminated and so, in turn, is most of the tropospheric fading which normally exists on a nonobstructed path.

ANTENNA ARRAYS

The fundamental principles of antennas for use at UHF and microwave ranges are the same as those for use at lower frequencies. These principles have been covered in Basic Electronics, NavPers 10087-B, and will not be included in this chapter. It is advisable that you become thoroughly familiar with the material in the basic course, for without such information you will probable experience a great deal of difficulty in understanding this chapter.

In order to increase the effectiveness of the antenna system, several elements are often combined to form an array.

The simple half-wave dipole may be used in a variety of combinations to provide directive radiation patterns, with a signal increase in some directions, but reduction in others.

The antenna array to be used will be determined by the requirements of the equipment and the particular purpose of the transmission. UHF directive arrays containing several parasitic elements may be built into a very small space. Likewise, directive arrays with parabolic and horn type reflectors which would be too bulky for use at the lower frequencies become very practical at microwave frequencies because of their small physical size.

Directional arrays are more widely used with radar than the simpler vertical or horizontal antennas because of the increased gain due to the concentration of energy.

DRIVEN ARRAY

In the driven array, each of the individual wires which comprise the array receives its energy from the transmitter. Driven arrays may be divided into three basic types—the broadside array, the end-fire array, and the collinear array.

Broadside Array

When two half-wave elements are placed one-half wave apart, parallel to each other and excited in phase, most of the radiation takes place in a direction perpendicular to a plane through the elements. The arrangement and radiation pattern of such an array, called a broadside array, are shown in figure 11-5.

The antenna elements are mounted one-half wavelength apart to simplify the problem of

937

Figure 11-5. —Broadside array.

feeding the array with a single transmission line. In one-half wavelength, voltage and current polarities reverse. Therefore, by reversing the connections between the antenna elements (as shown in fig. 11-5 (A)), all the elements in a vertical line may be fed in phase.

Because of the vertical mounting or stacking of the radiating elements, and because of the phasing of the currents and voltages, the vertical radiation from the array is small. Most of the energy is concentrated in the horizontal plane, and by using more elements in the array, this horizontal directivity can be further sharpened, as shown in 11-5 (C). This increased directivity is shown by the dotted lines.

End-Fire Array

When two elements are spaced a certain fraction of a wavelength apart and are excited out of phase by the same fraction of a cycle (as shown in fig. 11-6), the radiation is directional in the plane of the array and perpendicular to the elements. It is directional from the end of the array that has the most lagging current. If the spacing in an end-fire array, for example, is a half wavelength, the

Figure 11-6. —End-fire array.

two elements are excited a half cycle or 180° out of phase. This causes the bidirectional pattern shown in 11-6 (B). A unidirectional cardioid pattern can be obtained with a quarter wavelength spacing and a quarter cycle (90°) phase difference in excitation, as shown in 11-6 (C).

Collinear Array

A collinear array is formed when two half-wave elements are placed end to end and excited in phase. In a collinear array there is no directivity in the plane perpendicular to the antenna, but there is a sharp pattern in any plane containing the antenna. As with any of the other arrays, increasing the number of half-wave elements increases the directivity of the pattern. This array is shown in figure 11-7.

If radiation in only one direction is desired (and this is true in most radar installations) a metal screen is mounted behind the radiating

Figure 11-7. —Collinear array.

antennas. The unit now is a combination driven and parasitic array. This is a common procedure in the use of driven arrays, producing better directivity (and more antenna gain) than is possible with the driven array alone.

Interconnection of Elements in Arrays

There are several ways to connect the elements in an antenna array to obtain the required phase of excitation. The most convenient method to change the phase from one element to another element when they are a half wave apart is with an RF line. In the broadside array shown in (A) of figure 11-5, one element is excited directly from the transmitter. This element is connected to the other element by a half wavelength of RF line. The phase of the voltage along the RF line is shifted 180° for each half wavelength. The leads to the second driven element are reversed. This causes a reversal of polarity similar to that resulting from another 180° phase shift. The second element is then excited in the same phase as the first.

In the end-fire array in (A) of figure 11-6, the elements are also interconnected with RF lines. But instead of reversing the leads to the elements, they are connected directly to take advantage of the phase shift. With half-wave spacing, the interconnecting line will be one-half wave long and provide a 180° phase shift. If quarter-wave spacing is used, the interconnecting line will be one-quarter wave long; this arrangement produces a 90° shift.

The usual method for providing the correct phase in a collinear array is shown in (A) of figure 11-7. Since the current direction changes for each half wavelength of an antenna, it is not possible to connect the half-wave sections together directly. Instead, the half-wave section which carries the current in the wrong direction is folded to form a quarter-wave section of RF line. This brings together the ends of the sections in which current flows in the same direction. In other words, in terms of voltage it is necessary that the two antenna sections have voltages which are opposite in polarity at the open end. Further, note how the line to the transmitter is connected in the figure. The connection is made at a point of very high impedance. This requires the use of a resonant line. If a nonresonant line is to be used, it must be connected as shown by the dotted lines. In the diagram the connections near the closed end of the quarter-wave section are at a point of low impedance.

It is possible to connect any number of elements in this manner. Increasing the number of elements makes the array more directional.

PLANAR ARRAY

A planar array is a two-dimensional configuration of elements arranged to lie in a plane. (A linear array consists of elements arranged in a straight line in one dimension.) The two-dimensional planar array is probably the array of most interest in radar applications since it is fundamentally the most versatile of all radar antennas.

Radar beams can be rapidly scanned without any mechanical movement of antennas. Also, several independent beams can be generated simultaneously from the same antenna structure. When the array is mounted as a broadside array, the radiation pattern will be bidirectional and perpendicular to the plane of the array; with a reflector screen located a λ/4 behind the elements, the radiation pattern is undirectional. When the array is mounted as an end-fire array, the radiation pattern will be bidirectional and parallel to the plane of the array.

939

A rectangular aperture can produce a fan shaped beam. A square or a circular aperture produces a pencil beam. The array can be made to simultaneously generate many search and/or tracking beams with the same aperture (with the use of phase shifting devices).

PARASITIC ARRAY

A parasitic array is an antenna system which consists of two or more elements in which not all of the elements are driven. The other elements are excited by induction and radiation fields which are produced by the driven element. With parasitic arrays it is possible to obtain highly directional patterns. The action in a parasitic array is analogous to the action in a transformer in which the primary induces a current in the secondary and the current in the secondary produces a magnetic field which, in turn, induces current back into the primary. The phase relationship between elements in an array varies according to the spacing between elements. The elements are usually spaced an appreciable fraction of a wavelength apart.

Antenna with Reflector

In the two-element array shown in figure 11-8 (A), the DRIVEN ELEMENT is cut at the center for connecting a low impedance feed line. The length of the driven element is a half wavelength. This makes it self-resonant. A parasitic element (called the REFLECTOR) is located 15 percent of a wavelength in space from the driven element, and is about 5 percent longer than the driven element.

If the polar diagram is plotted for two elements spaced 0.15 wavelength apart and excited out of phase, the curve shown in (A) results. This shows that most of the radiation is on the side of the driven element which is away from the parasitic element, while very little occurs on the side of the reflector.

Another point is that the field passing from the reflector cuts the antenna (driven element) and induces a voltage in it. This voltage changes the input current. The input impedance, which is a function of this current, is about 50 ohms as compared to 73 ohms for the antenna alone.

Antenna with Director

A parasitic element becomes a director when it is made shorter than the antenna element. In a director most of the energy is sent in a direction from the antenna element to the parasitic element. To see what takes place, note

Figure 11-8.—Parasitic antennas and arrays.

the radiation pattern and the arrangement of the array in the diagram in (B) of figure 11-8. The director is usually about 5 percent shorter and about 0.1 wavelength from the antenna. Sometimes the impedance is reduced to 20 ohms at the driven element in this array.

Multielement Yagi

Notice the element array called a Yagi antenna in (C) of figure 11-8. In it the antenna or driven element is insulated, but the reflector, and all directors are welded to a piece of tubing which runs parallel to the direction of propagation. The beam width of this array is about 19°. The four-element Yagi shown in (D) is constructed similary to the one in (C) and has a beam width of about 50°.

Phase Relationships

Figure 11-8 (E) shows the phase relationship in the parasitic array vectorially. Vector i_d, which represents the current in the driven element, is in phase with the H-field. The part of the H-field that cuts the parasitic element lags the field which leaves the driven element by 0.15 of a cycle. (This is the time lapse during the travel between elements.) The lag is equivalent to 54°. The flux at the reflector is shown by vector ϕi. It lags i_d by 54°. The voltage induced by the field is 90° out of phase with the field. This voltage is represented by the vector E_p. If the parasitic element were resonant, the current in it would be in phase with E_p, but the reflector is longer than the resonant half wavelength. A long antenna is inductive and the current in this element will lag the voltage by 36° if it is approximately 5 percent longer. The radiated field will be in phase with this current. In summary, the field starting out from the parasitic element will be 180° out of phase with the field leaving the driven element.

Directivity

The conventional method for describing the directivity of an antenna array is in terms either of the ratio of the power in the best lobe to the power radiated by a simple half-wave antenna (antenna gain), or the ratio of the power in the direction of the best lobe to the power in the opposite direction (front to back ratio). The direction of the best lobe is usually called FORWARD direction, while that in the opposite is called the BACKWARD direction. In other words, this ratio is the power in the forward field to the power in the backward field. For example, the front to back ratio of the antenna array illustrated in (B) of figure 11-8 is about 5:1. In decibels, this represents approximately a 7-db gain. The ratio between forward power and power from a single half-wave antenna is about 4 db.

Comparison between the more directive types of arrays are made in terms of the beam angle. This angle is the angle between half-power points in the main lobe (radiation curve). In arrays the half-power points are the points where the electric field strength (volts per meter) is 0.707 times as great as that along the axis of the beam. Figure 11-9 shows the beam angle for a radiation pattern. In this illustration the angle between points A and B (angle ϕ) is the beam angle. At each of these points the signal strength is 70.7 percent of its value at point C. At A and B the power radiated is one-half the value as at C; thus these points are also known as half-power points.

Figure 11-9.—Beam angle.

Power Gain

Figure 11-10 shows the effect of the element spacing on the power gain of an array as compared to the field strength of a half-wave antenna alone. Curve A shows the power gain for director spacings in wavelengths between a half-wave director and the driven half-wave radiator. Curve B shows the power gain for half-wave reflector spacings between the reflector and the driven half-wave radiator.

The graph shows that when a single parasitic element is used, there is little difference in the gain of the array if the parasitic element employed is used either as a reflector or as a director. When the parasitic element is tuned to work as a reflector, the spacing which gives maximum gain is about 0.15 wavelength and this maximum gain peak is fairly broad. The director will give slightly more gain than the reflector, but the difference between the two is less than 0.5 db. Consequently, on the basis of gain, there is little choice between the two types of operation. The broader curve of the reflector does offer a distinct advantage in that the spacing is less critical. Similarly, a small error in reflector spacing will reduce the gain of the array less than the same spacing error in a director type array. For this reason, when a single element is used, the array is usually a reflector type array.

Several parasitic elements can be used in conjunction with a driven antenna to increase further the directivity and power gain. The theoretical power gain of directional antenna arrays composed of an excited element and various numbers of parasitic elements is given in table 11-3.

Figure 11-10. —Relative power gain for parasitic elements.

Impedance Considerations and Matching

In multielement arrays the input impedance drops as low as 15 ohms. In these arrays special matching devices are needed for matching this low impedance to the higher impedance of most RF lines.

One method for making the match is to use the delta matching system in which the end of the transmission line that is to be connected to the antenna is spread apart (fanned out) before being connected. The section of the line that is spread apart has a continuously increasing characteristic impedance. The impedance of a half-wave radiator increases from 73 ohms in the center to about 2,500 ohms at the ends. Thus, the impedance at any point is determined by the distance from the center. Two points can be found on the radiator where the impedance equals that of the fanned section of the transmission line. The connections are made at these points.

Another method, the one most often employed, uses the folded dipole as shown in figure 11-11.

A folded dipole is a full wavelength conductor which is folded to form a half-wave element. (A better description is that it consists of a pair of half-wave elements connected together at the ends.) In it the voltage at the ends of each element must be the same. In operation, the field from the driven element induces a current in the second element. This current is the same as the current in the driven element.

An ordinary dipole with a given current, I, produces a certain field intensity in space. Due to this field, there is also a certain power density per square meter in space. This power

Table 11-3. —Theoretical power gain.

Number of elements	Power gain
2	2.5 (4.0 db)
3	3.6 (5.6 db)
4	5.0 (7.0 db)
5	6.4 (8.1 db)

942

Folded Dipole

Figure 11-11. —Folded dipole antenna array.

density is produced by the input power, P. The relationship between the input resistance, the current, and the input power is expressed by the equation,

$$R = \frac{P}{I^2}$$

With the folded dipole, the same current, I, exists at the input terminals; but this same current flows in both sections of the antenna, and consequently, the field strength in space is doubled. This causes the power density per square meter to increase to four times the previous value when the current at the input remains unchanged. In turn the input power must be four times as great. In this case, to balance the equation, it is necessary to multiply R by 4 as follows:

$$\frac{4P}{I^2} = 4R$$

So long as each section of a dipole has the same diameter, the input resistance is four times that of the simple half-wave dipole. Increasing the diameter of one section makes the increase in impedance still greater. The input impedance to the driven element of a parasitic array drops to about a fourth of the value of the coaxial cable impedance, but the use of a folded dipole increases the impedance by about four times. In this way a good impedance match is achieved.

PARABOLIC REFLECTOR

When a multielement broadside array is excited, the E-field which exists in front of the antenna will be a single plane, as shown in (A) of figure 11-12, rather than in an arc as is the case in a single half-wave element. The larger the dimensions of this plane in terms of wavelengths, the greater is the directivity of the antenna system, and the narrower the radiated beam.

Although a multielement broadside array gives good results, it is quite complicated in structure. In it every element must be driven and all spacings and dimensions must be quite exact. A much simpler device for producing an electric field in a single plane is the parabolic reflector. As shown in (B), the parabola has its focal point at F. If a single antenna is placed at F and caused to radiate a field, the electric field will leave the antenna in all directions at the same rate in the form of an arc as indicated at point A. As each part of the wavefront reaches the reflecting surface, it is shifted in polarity and sent outward at an angle of reflection that is equal to the angle of incidence. All parts of the field will arrive at line BB' at the same time after reflection because all paths from F, to the reflector, to line BB' are equal in length. Thus, with only one antenna and a specially shaped reflector, it is possible to produce a large electric field in a single plane. Or, looking at it another way, all parts of the field travel in parallel paths after reflection from the para-

943

Figure 11-12.—Directional radiation by means of reflectors.

bola in such a way that the rays are focused like the headlight beam from an automobile.

Like the broadside array, high directivity is not obtained until the diameter of the parabolic reflector is made many wavelengths long. This prohibits the use of the parabolic reflector at low frequencies, but for 3-centimeter and 10-centimeter radar equipment these reflectors are very practical.

Feed Systems

In figure 11-13 (A), showing the exciting antenna for a parabolic reflector, the half-wave dipole is mounted a quarter wave back from the short on the coaxial line. To sharpen the focal point, the antenna is made physically less than a half wave long. However, the balls at the end make it electrically a half wave long. This broadens the band of frequencies it will handle. The airtight cylinder in which the antenna is enclosed permits the coaxial line to be pressurized. The inner surface of half the cylinder on the side away from the parabolic reflector, is coated with a reflecting foil. This reflecting surface directs energy from that side of the antenna into the large reflector. Without this reflector, the antenna radiation would be nondirectional.

The natural directivity of a dipole causes the pattern from a parabolic reflector to be somewhat sharper in the plane containing the dipole than in the other plane. For this reason, the dipole is erected horizontally for maximum azimuth accuracy in radar systems. If vertical accuracy is of primary importance, the dipole is mounted vertically.

Other methods of preventing the direct forward radiation use a parasitic reflector with the half-wave dipole, and a disk which is placed in front of the dipole.

A waveguide can be used to bring energy to the parabolic reflector by placing the mouth of the guide at the focal point of the parabola and positioning it so that the energy strikes the parabolic reflector. A typical application is shown in (B). The most easily constructed waveguide feed is simply an open-ended waveguide. The energy from the transmitter comes streaming down the guide, passes out through the open end and, if this is facing the parabolic reflector, strikes the reflecting surface. Sometimes the end of the waveguide is tapered, so that the energy may be distributed horizontally or vertically to produce a desired pattern after it is reflected by the paraboloid. By modifying the shape of the feeding waveguide, this energy can be concentrated in one direction

Figure 11-13.—Feed systems for parabolic reflectors.

and, in conjunction with the parabolic reflector, achieve a desired radiation pattern.

One difficulty that is encountered when using waveguides to feed energy to parabolic reflectors is the fact that the guide, passing in front of the reflector, tends to block part of the energy reflected by the paraboloid. To avoid this difficulty, several rear feeds have been developed. In this form of feed, the waveguide passes through the vertex of the paraboloid and extends to the focus, at which point the energy is redirected back to the reflecting surface of the paraboloid and then radiated in the forward direction. The most widely used and most successful of these "rear-feed" arrangements is the Cutler feed shown in (C).

The waveguide is terminated in front of the reflector in a Cutler feed radiator, which in reality is a cavity at the end of the waveguide. It can be considered as two small waveguides formed as a result of dividing the main wave into two halves, and bending each half through 180°. The fields emerge from openings or slots that are a half wave apart as shown in the drawing. The waveguide is tapered in the noncritical dimension to fit between the slots. The cavity impedance is matched to the waveguide by the matching screw. This adjustment is made at the factory and soldered in position. The radiated field is horizontally polarized. The design of the cavity is such that the energy striking the reflector decreases sinusoidally from the center toward each edge.

Variation of Parabolic Reflectors

It is possible to concentrate energy in one plane only, by using a section of a parabolic reflector. Thus, with the parabolic cylinder shown in figure 11-14 (A), directivity is obtained in the plane perpendicular to the length of the cylinder. In the figure, this would mean sharp vertical directivity. Parabolic cylinders do not have single focal points as paraboloids do, but rather a focal line. Small dipole antennas are mounted along this line, the useful energy radiating back toward the reflector and then forward by reflection from the surface. The horizontal directivity of this reflector is determined by the number of half-wave dipoles used and the phasing of the currents and voltages fed by a transmission line to the dipoles. The greatest directivity, however, is obtained in the vertical plane and this is determined by the parabolic surface.

Another section of a paraboloid which is of interest is the truncated paraboloid shown in (B) of figure 11-14. This is energized by either a single dipole or a waveguide placed at the focal point. Directivity in the horizontal plane is essentially the same as that obtained from a paraboloid; directivity in the vertical plane is not quite as good. This type of antenna would be suitable for ground to air or ground to ground surface search.

Figure 11-14. —Variations of the parabolic reflector.

When a waveguide is used in the RF system, it is possible to send the energy into the parabolic reflector with a horn radiator. In this case an orangepeel reflector (fig. 11-14 (C)), or section of a complete circular paraboloid may be used as the reflector. The feed is by a waveguide and a horn type radiator. The horn type radiator and orangepeel parabola are constructed so that almost all of the energy that the horn radiates is intercepted and reflected by the reflector. This arrangement is highly directive in the vertical plane and is used principally to determine the altitude of aircraft.

Cosecant-Squared Reflectors

Because of the variety of the applications of radar, widely different requirements must be met by different antennas. Antennas designed to produce special polarization effects or pattern shapes may differ greatly from those already described. In airborne radar sets that are designed for use in scanning a large area, a special beam shape is required.

This beam should be narrow in the horizontal plane, but broad in the vertical plane. In addition, the particular section of the area being scanned must not be uniformly illuminated by the radar beam. Instead, the objects near the aircraft should be illuminated by less power than those farther away in the same sector, because echo signals from nearby objects will be strong due to their closeness to the plane. On the other hand, a greater amount of power should fall on more distant objects in this sector, since they would normally produce the weakest echoes. Thus, the radiated field of the beam should increase in intensity at the greater distances. Figure 11-15 (A) shows some trigonometrical relationships of this situation.

If the aircraft is at point A in figure 11-15 (A), and the target is at point B, then the slant range (straight-line distance from A to B) can be represented in terms of the aircraft altitude (h) and the angle of depression (θ) of the target as seen from the aircraft:

$$\frac{h}{r} = \sin\theta; \quad r = \frac{h}{\sin\theta}; \quad r = h \csc\theta$$

Thus the slant range is proportional to the cosecant of θ.

946

Figure 11-15.—Cosecant-squared antenna and pattern.

An antenna has been designed so that the field intensity pattern is also proportional to cosecant θ; this antenna lays down a uniform electric field which causes the echo response of a nearby target to be approximately equal to that of a distant target having the same radar cross section (reflectivity). The equality of response is based on the concept of power density; research has shown that power density is proportional to the square of field intensity. This particular antenna, therefore, produces an electrical field whose power density is proportional to the square of cosecant θ.

Recalling from a review of Basic Electronics, NavPers 10087-B, that RF signal strength is inversely proportional to the square of the distance from the source, note that a balance of signal loss against signal gain is utilized in this antenna. As the slant range r (fig. 11-15 (A)) increases, θ decreases and csc θ increases. The signal strength (power density) is inversely proportional to the square of h csc θ because the wave is RF energy; at the same time, the signal strength is directly proportional to the square of csc θ because of the antenna design. (Assume that h is constant.) The result is a net change of zero (theoretically) in the signal strength up to the maximum range of the transmitter. The antenna design which produces this result is called the cosecant-squared antenna.

Figure 11-15 (B) shows the special paraboloid reflector, in which the top portion is bent forward to produce the cosecant-squared pattern. Also shown is the pattern itself. Notice that this antenna produces a field of constant signal strength (bounded by the white line)

at ground level (line XY) over a broad range of values of θ.

This same type of antenna is also used (in an inverted position) on the land based and shipboard systems for obtaining equal indications from aircraft at equal altitudes but different ranges

Another type of reflector is shown in figure 11-16. This reflector differs from the one just discussed in that it is capable of producing either a pencil type (narrow beam both vertically and horizontally) or a cosecant-squared pattern. Mounted on the reflector is a rod grating, roughly shaped in the form of a barrel stave, which is polarized and acts as a spoiler to deform the pencil beam pattern into an equal energy return (cosecant-squared) pattern. The choice of pattern desired may be obtained by rotating the entire reflector and grating 90° by means of a motor and gear train. In the position where the spoiler is nonreflective, a pencil beam pattern is produced. In the position where the spoiler is reflective, a narrow, blade-like pattern having equal energy return results.

Figure 11-16.—Parabolic antenna with spoiler.

Some reflectors of this type are equipped with a solid spoiler that is hinged to the upper part of the paraboloid. The desired pattern may be obtained by causing this spoiler to tilt out of the reflector to a position where the cosecant-squared pattern is produced. In the retracted position the spoiler is flush with the surface of the paraboloid and a pencil beam is produced.

TYPICAL AIRBORNE ANTENNAS

Until the past few years, the antennas used in airborne electronics were fairly standard. For a transmitter operating within a given frequency band, the same antenna was used as a standard installation item in all types of aircraft. With the modern concept of the weapons system, however, the electronic equipments and their antennas are designed along with the individual weapons system. This eliminates the interchangeability of antennas from one system to another. However, since the antenna is designed for a single specific application, it has decreased considerably in importance as a major source of trouble.

Although the antennas used with specific equipments in specific weapons systems are somewhat different from one another, they have certain basic similarities. There are general classes of antennas used, each for its own specific purpose. The various antenna components of the electronic packages are merely modifications of these basic types. The remainder of this chapter is devoted to a discussion of these types; some specific examples are mentioned, along with some of the new developments in antenna design.

The location of the antenna will vary depending upon the specific problems of the installation. It is extremely important to know that at all frequencies, especially UHF and microwave, it is possible to reduce the efficiency of an installation through the use of excessive antenna cable lengths and connectors. Antenna runs should be kept to a minimum length. In most cases the Service Instruction Manual will specify maximum lengths. It is also important that either the designated type or a

lower loss cable be used in all installation work.

A helpful publication, Index of RF Transmission Lines and Fittings, MIL-HDBK-216, is available upon request. This publication contains charts of attenuation versus frequency for various types of transmission lines, assembly data for connectors, waveguide data, and other information. The charts will be helpful in determining attenuation losses for an antenna cable at a particular frequency. An example of attenuation loss is as follows: RG8/U cable has an attenuation of 9 db per 100 feet at 1,000 megacycles. If a 1,000-watt transmitter is connected to an antenna with 33 1/3 feet of cable, the power at the antenna will be only 500 watts; thus, half the power is dissipated by the cable. It is also possible to increase the losses of the system by using older type high loss connectors. Even with the newer type low loss connectors, it is advisable to use as few as possible. This may be partially accomplished by using a minimum of right angle connectors and as few as possible of the type that connect through the bulkhead. Adaptors should also be used sparingly.

GROUND-PLANE ANTENNAS

A vertical quarter-wave antenna several wavelengths above ground produces a high angle of radiation which is very undesirable at the VHF and UHF frequencies. An effective means of obtaining a low angle of radiation from this type antenna is to work it against a simulated ground (called a GROUND PLANE). The simulated ground may be made from a large sheet of metal, or from several wires or rods protruding from the base of the radiating element of the antenna. In another type, the outer conductor of a coaxial antenna may be flared out. An antenna so constructed is called a ground-plane antenna. The most noticeable difference between the ground-plane antenna and the reflector type antenna is the relative positions of the elements. In the reflector type antenna, the reflector element is mounted parallel with the driven element; while in the ground-plane antenna the ground plane is mounted perpendicular to it.

Several types of ground-plane antennas are shown in figure 11-17. The radius of the ground sheet or the length of the rods used should be one-quarter wavelength or longer. The function of a ground plane corresponds to that of a counterpoise used with low frequency vertical antennas.

This type antenna is frequently used with VHF and UHF communications equipment in aircraft. The skin of the aircraft serves as the ground plane. When this type antenna is used with a ground installation, it is necessary to employ a ground plane as illustrated. Without the use of the ground plane, it is impossible to obtain proper loading and efficient radiation.

Since there are no ordinary transmission lines having a characteristic impedance low enough to permit a direct connection to the 20- to 36-ohm impedance of the ground-plane antenna, a quarter-wave matching section may be used to obtain an acceptable match.

If it is desired to avoid the use of a matching section with its accompanying power losses and bandwidth limitations, the radials can be arranged to slope downward in the manner of an inverted cone as shown in (C). The impedance increases as the angle between the radials and the horizontal plane increases. This method can be used to secure a suitable match to a 52-ohm transmission line. It is possible to use the rods or cables in the multiple capacity of a ground plane and as guy wires for mechanical support, while at the same time changing the impedance to obtain a proper match.

The impedance can be increased further to match a 72-ohm line by bending the radials down parallel to the transmission line, or by supporting the shaft as shown in (D).

SLEEVE ANTENNAS

The sleeve antenna is basically a vertical omnidirectional antenna developed from the ground-plane antenna by folding the ground plane back over the radiator (to form a sleeve) before flaring it out. This helps to minimize radiation from the feeder line. One type coaxial radiator is one-half wavelength long, with the top half a thin whip or rod, and the bottom half a comparatively large hollow metal tube or cylinder. The coaxial feed line is run up through the sleeve radiator or cylinder, as shown in (A) of figure 11-18. The center conductor of the coaxial line connects to the whip radiator, and the outer conductor connects to the sleeve radiator. Since there is no RF field within the sleeve, interaction between the radiator and the coaxial line is minimized.

Figure 11-17. —Ground-plane antennas.

The section of transmission line within the sleeve acts in conjunction with the sleeve to form a short circuited concentric line which has an extremely high impedance across the open end. This high-Q parallel resonant circuit minimizes coupling between the sleeve radiator and the transmission line or hollow supporting mast. Although the sleeve effectively decouples the section of line within it from the sleeve radiator itself, as well as from the upper radiator, there will still be some coupling between radiators and the section of transmission line or mast immediately below the sleeve. This coupling causes some radiation from the vertical portions of the line and/or mast, and as a result, some power is wasted in high angle radiation.

Radiation can be eliminated from the feeder and mast by placing a quarter-wave detuning sleeve below the sleeve radiator as shown in (B). The detuning sleeve is mounted with its open end facing upward, one-quarter wavelength below the bottom of the sleeve radiator. Its closed end is connected to the mast, or to the outer conductor of the coaxial feed line.

Inasmuch as the coaxial antenna is effectively a vertical, center fed, half-wave radiator, its center impedance is approximately 70 ohms. A 70-ohm feed line provides the most efficient match, but lines up to 120 ohms can be used without serious mismatch. It is possible to maintain a uniform impedance over a larger frequency band by increasing the diameter of

950

Figure 11-18.—Sleeve antennas.

the dipole, or by using a dipole constructed in the shape of a cone or cylinder.

CORNER REFLECTOR

When a unidirectional radiation pattern is desired, such a characteristic can be obtained by the use of a corner reflector. A corner reflector antenna is a half-wave radiator with a reflector consisting of two plane metal surfaces meeting at an angle immediately behind the radiator. In other words, the radiator is set in the plane of a line bisecting the corner angle formed by the reflector sheets. The construction of a corner reflector is shown in figure 11-19 (A).

Corner reflector antennas are mounted with the radiator and the reflector horizontal when horizontal polarization is desired. In such cases, the radiation pattern is very narrow in the vertical plane, with the maximum signal being radiated in line with the bisector of the corner angle. The directivity in the horizontal plane is approximately the same as for any half-wave radiator having a single-rod

Figure 11-19.—Corner reflector antenna.

951

type reflector behind it. If the antenna is mounted with the radiator and corner reflector vertical (as shown), maximum radiation is produced in a very narrow horizontal beam. Radiation in a vertical plane will be the same as for a similar radiator with a single-rod type reflector behind it.

At frequencies in the VHF and UHF bands, the corner reflector is often made from solid metal sheets. At lower frequencies, such sheets are massive and are easily damaged by high winds. Therefore, screen wire or metal rods located in the plane of the reflector sheets and running parallel to the radiator are used instead. The spacing between the rods must not be more than 0.06 wavelength at the operating frequency.

The gain and the radiation resistance of a corner-reflector antenna are both affected by the reflector corner angle Φ and the spacing, d, between the radiator and the corner as shown in (A), as well as the construction of the antenna and reflector. The gain (expressed as a power ratio between the dipole with a reflector and the dipole alone) for several corner-reflector antennas is shown in the graph in (B). Here the gain is shown for various spacings between the dipole and the corner reflector, and for an angle Φ of 90°, 60°, and 45°.

Sometimes the corner reflector is used as a PASSIVE RADIATOR. Under these conditions, the reflector is not excited by a dipole that is mounted with the reflector. Instead, the reflector is acted on by a distant transmitting antenna. Here, the purpose of the corner reflector is to return the greatest amount of energy possible back in the direction from which it originally came.

The most important use of the corner reflector as a passive radiator is in radar applications. Here, it is sometimes necessary to make good radar targets from objects which do not ordinarily reflect back enough of the transmitted radar beam to disclose their presence. For example, it is normally very difficult for a search radar to locate a rubber liferaft, particularly in a rough sea. If a corner reflector is installed on the raft, then it becomes possible for an aircraft radar to detect the raft over a distance of many miles. Corner reflectors are also used to mark the edges of landing fields or a particular runway so as to provide a well marked point for the aircraft or ground radar equipment. Corner reflectors are frequently installed on important buoys or strategic points of land which would otherwise not be good radar targets.

The appearance of a corner reflector used for marking radar targets is shown in figure 11-19(C). Three mutually perpendicular metal surfaces similar to the arrangement of the floor and two sidewalls at a room corner are used. It should be noted that in the passive corner reflector the corner angle Φ is always 90°. If a radar beam is directed into the reflector, reflections may occur from all three surfaces, from two surfaces, or from one surface, depending on the angle of arrival of the beam. In any case, the reflections cause the radar beam to be returned in the direction from which it came. Under these conditions, the radar antenna picks up the reflected energy and detection occurs.

A single corner is effective only for energy that arrives from directions covering one octant of a sphere centered at the reflector. If it is desired to have coverage in all directions (such as would be the case for liferaft detection), then a cluster of eight such corner reflectors is used.

The size of such reflectors is not critical so long as the length of a short side is many wavelengths long at the frequency of the detecting radar. The corner reflector cluster which is included as part of the emergency rescue equipment on liferafts is a collapsible structure made of screen and measuring 2 feet on a short side. The reflector is mounted about 4 feet above the raft.

SLOT ANTENNAS

Slot antennas are adaptable for the VHF and UHF ranges. Their most important practical advantage is that the feed section which energizes the slot may be placed below the large metal surface in which the slot is cut. Thus, nothing need protrude from the surface. In addition, the slot itself may be covered by a section of insulating material so that the opening is closed. As a result, no air resistance occurs. This is particularly important in the case of high speed aircraft where the vibration problems and drag that would be introduced by conventional antennas cannot be tolerated.

When a slot antenna is installed on an aircraft, particular attention should be paid to the slot location with respect to large protuberances.

Wings, fuselage, or engine will act to cut off a large portion of the energy radiated from a slot if these objects are located between the slot and the receiving location. Optimum locations for slot antennas on aircraft include the leading edge of the wing and the side of the nose.

Basic Slot Antenna and Its Complementary Dipole

The slot antenna consists of a radiator formed by cutting a narrow slot in a large metal surface. Such an antenna is shown in figure 11-20. The slot length is a half-wave while the width is a small fraction of a wavelength. Such an antenna is frequently compared to a conventional half-wave dipole consisting of two flat metal strips whose sizes are such that they would just fit into the slot cut out of the large metal sheet. This type is called the COMPLIMENTARY DIPOLE. This comparison is made since the radiation pattern produced by the slot antenna when cut into an infinitely large metal sheet and that of the complementary dipole antenna are the same.

It is of interest to note several important differences between the slot antenna and its complementary antenna. First, the electric and magnetic fields are interchanged. In the case of the dipole antenna shown, the electric lines are horizontal while the magnetic lines form loops in the vertical plane. With the slot antenna, the magnetic lines are horizontal and the electric lines are vertical. The electric lines are built up across the narrow dimension of the slot. As a result, the polarization of the radiation produced by a horizontal slot is vertical. If a vertical slot is used, the polarization is horizontal.

Figure 11-20.—Slot and complementary dipole antennas.

A second difference between the slot antenna and its complimentary dipole is that the direction of the lines of electric and magnetic force reverse abruptly from one side of the metal sheet to the other. In the case of the dipole, the electric lines have the same general direction while the magnetic lines form continuous closed loops.

When energy is applied to the slot antenna, currents flow in the metal sheet. These currents are not confined to the edges of the slot but rather spread out over the sheet. Radiation then takes place from both sides of the sheet. In the case of the complementary dipole, however, the currents are more confined, so a much greater magnitude of current is required to produce a given power output.

From this it may be seen that the current distribution of the dipole resembles the voltage distribution of the slot, and conversely. The edges on the slot have a high voltage concentration and relatively low current distribution; the complementary dipole has a quite high current concentration and relatively low voltage.

Coaxial Feed of the Slot Antenna

A coaxial line is frequently used to feed the slot antenna. The outer conductor of the feed line is bonded to the metal sheet while the inner conductor is connected to the opposite side of the slot as shown in figure 11-21. Note that the coaxial line is not connected at the center of the slot length since a severe impedance mismatch would occur.

The impedance at the center of a slot whose electric length is a half wave is 530 ohms. This impedance is reduced to a lower value as the input connection is moved toward the end of the slot. At a point about one-twentieth of a wavelength from either end, the input impedance falls to about 50 ohms. A coaxial

Figure 11-21.—Feeding slot antenna with coaxial line.

line may thus be connected here without serious mismatch. The slot length may be increased to a full wave if it is desired to connect the coaxial line to the center of the slot. With a full wave slot, the input impedance at the center of the slot is 50 ohms.

Boxed-in Slot Antenna

Frequently, it is desired to produce radiation from only one side of the metal sheet in which the slot is cut. This is conveniently arranged by boxing in the slot with a section of waveguide. If the depth of the waveguide is a quarter wave (fig. 11-22), then the waveguide will introduce no reactance. Under these conditions, the input impedance at the center of the slot is about 1,000 ohms and the impedance at a point about one-twentieth of a wavelength from either end is about 100 ohms.

Waveguide-Fed Slot Antenna

Another convenient method of making a slot antenna radiate from only one side of the metal sheet in which it is cut is to energize the slot by means of a waveguide as shown. This does away with the coaxial feeder altogether.

Figure 11-22.—Unidirectional slot antennas.

Radiation Patterns.

It has been mentioned that the radiation pattern produced by a slot antenna is the same as that produced by a complementary dipole antenna. This is true only if an infinitely large metal sheet is used. As the width of the metal sheet is reduced, the amount of radiation that occurs at small angles to the plane of the metal sheet is reduced considerably. This is shown in figure 11-23. The radiation pattern produced by a complementary dipole antenna in the plane perpendicular to the antenna is also shown for comparison. In this pattern, you are looking at the end of the dipole. If all radiation disappeared to the left of the vertical centerline shown in the illustration, then you would have the radiation pattern produced by a boxed-in slot antenna. (See (A) of fig. 11-23.) Here you are looking along the edge of the metal sheet in which the slot is cut. The length of the slot is at right angles to the plane of the page and the radiation patterns shown are in the plane of polarization of the energy.

If the width of the metal sheet is a little over 5 wavelengths, then the scalloped pattern shown in (B) results. As the width of the sheet is further reduced to slightly over 2 1/2

Figure 11-23.—Radiation from boxed-in slot antenna.

wavelengths, fewer irregularities appear in the pattern, as shown in (C). Also note the reduced radiation at a fixed angle (say 30°) with respect to the metal surface. At a width of only about a half wavelength, the pattern shown in (D) bears only a little resemblance to that shown in (A). The radiation produced at an angle of 30° is further reduced. In practice, since the size of the metal surface in which the slot is cut is usually quite large (compared to a wavelength), radiation patterns having a form somewhere between that shown in (A) and (B) are common.

T-Fed Slot Antenna

A type of slot antenna which was developed for use over a very wide frequency band and which could be fed by coaxial line is shown in figure 11-24. With the compensating bar (providing capacitive loading) and stub as shown, this antenna has a standing wave ratio of less than 2 to 1 over a frequency range from about 30 percent below to about 30 percent above the design center frequency when fed with 50-ohm coaxial cable. Such an antenna may be constructed in a large flat metal surface or it may be made to conform with a curved metal

Figure 11-24.—T-fed slot antennas.

955

surface. For example, the curved slot antenna shown in (B) can be installed in the leading edge or tip of an aircraft wing. With such a severely curved large metal surface, the radiation pattern produced is quite different from that produced with a slot in a flat surface. The extent of the curvature has considerable effect on the radiation produced.

Slot Array

Still another form of the slot antenna is shown in figure 11-25. Here the large metal sheet is eliminated completely. Instead, an array of diagonal slots is cut into a length of waveguide. The slots are spaced at intervals along the waveguide so that they are excited in phase. Maximum radiation takes place in the direction indicated.

SKIN ANTENNA

A skin antenna is a type of flush mounted antenna used in aircraft. Such antennas are generally used in high speed aircraft where it is necessary to eliminate the speed reducing aerodynamic drag produced by the usual types of antenna installations. The skin antenna is made by electrically isolating a portion of the metal skin of the aircraft and using this section as the radiating surface of the antenna. In one type of installation, a plastic section insulates the metal skin at the wingtips from the rest of the skin of the aircraft as shown in figure 11-26. The wingtip section connects to the receiving and transmitting equipment through an impedance matching network and coaxial cable.

The range of a skin antenna approximates that of fixed wire antennas for the same frequency coverage. Although the illustration shows a wingtip installation, skin antennas can also be made a part of suitable tail or fuselage surfaces. The radiation patterns depend on the operating frequency, the size of the radiating surface, and the location of that surface on the aircraft.

Figure 11-25. —Slot array.

Figure 11-26. —Wingtip antenna.

Other types of flush mounted antennas which find wide use in VHF and UHF aircraft communications and radar installations consist of loops, dipoles, and parasitic and driven arrays encased in plastic housings or canopies forming the tip or a part of the surface of a wing, elevator, stabilizer, or nose.

UHF BROADBAND ANTENNAS

The so-called "broadband antenna" is a representative of a class of low-Q antennas that will operate with fairly constant effectiveness over a wide range of frequencies. Electronic countermeasures (ECM), frequency modulation (FM), pulsed radar altimeters, and other equipments have used this type antenna effectively. In order to be of maximum effectiveness, passive ECM must receive and respond to any signals over a wide frequency range. This reception must be rapid, with a minimum of tuning adjustment.

The antenna itself is normally a half-wave dipole, made thick and stubby in order to give the antenna a low inductance, a low L-to-C ratio, and the low Q that results from these. Being a tuned circuit, the antenna will have a wider frequency response with less gain than an equivalent antenna with a higher Q. Another factor that will add to the wide uniform response is the method of support. Normally this support will be a quarter wave shorted

section of transmission line. In addition to the insulating qualities of the transmission line section, the support may be used as an impedance matching device, and also as a tuning stub.

Since the antenna acts the same as an open-ended quarter-wave section of transmission line, any increase in frequency will tend to cause the antenna to become inductive, and the support to become capacitive. This opposing action results in the antenna appearing resonant over the wider frequency range. Lowering the frequency will cause opposite actions, and broader response.

The assembly will normally include built-in impedance matching devices which are relatively insensitive to frequency variations.

The antenna itself may be a half-wave dipole, of which there are many types. The type that provides the ultimate in broadband response is the flared coaxial antenna of the type shown in figure 11-27 (A). The inner and outer conductors are both flared, but in order to maintain a constant impedance throughout the full range of frequencies, the ratio of the inner to outer diameter is maintained constant. The more gradual the flare of the diameters, the less reflection of mismatched impedances, and the more constant the efficiency of the antenna.

By folding the outer conductor of the coaxial antenna to form a ground plane, and shaping the inner conductor to a teardrop configuration (as in (B)), an antenna is obtained that has a frequency response nearly as good as the original broadband type discussed above.

The actual radiator of the broadband antenna may take any of several shapes, depending on the desired broadness of the band, directional characteristics, impedance, etc. In general, the greater the thickness of the radiating element, the broader the pass band. Thus, radiators having conical or cylindrical shape are less broad than those previously discussed, while the thin stub (or whip) is even more narrow in its frequency response.

In the coaxial feed and antenna system, the ratio of diameters (outer to inner) is sometimes changed. When this is done, the resulting impedance mismatch reflects energy back down the line. This mismatch may be fairly abrupt, being more so as the antenna is made thinner or as the change in the ratio is made more abrupt. The frequency band is determined by those frequencies at which the impedances are sufficiently matched and the reflection cancel.

The antenna required for a broadband response could also be developed from the two-wire transmission line (as shown in (C) of figure 11-27), but the frequency response is not quite so broad as for the equivalent coaxial antenna.

Figure 11-27.—Broadband antennas.

Blade Antenna

An ultrahigh frequency, streamlined, blade shaped broadband antenna for general purpose use over the 225- to 400-megacycle range is shown in figure 11-28 (A). An antenna of this shape may consist essentially of a near quarter-wave stub fed through the base, or it may be a sleeve type antenna. It is designed for mounting on the exterior skin of the aircraft, and so it is streamlined for high speeds. Its cross sections take the form of ellipses on the leading half of the body, and of parabolas on the trailing half. The resulting form has minimum drag effect.

This antenna is usually a single self-contained unit. No accessories are required other than those for mounting and connecting.

A single broadband antenna of this type may be connected to two or more pieces of equipment operating on different frequencies within the range of the antenna. When this is done,

Figure 11-28.—Typical aircraft antenna assemblies.

958

it is necessary to use bandpass filters in series with the antenna cables to isolate the equipments.

Cone Antenna

It frequently becomes desirable for a transmitting or receiving antenna to operate over a wide band of frequencies. This is especially true in electronic countermeasures and airborne communication equipment. In order to operate over a wide band, it is necessary that the characteristics of the antenna system be such that the radiation pattern is not appreciably changed over the frequency range involved. It is also necessary that the standing wave ratio be held to a minimum in order to prevent excessive losses.

The impedance of resonant wire antennas will vary with frequency, thus they will function adequately over only a narrow frequency band. As previously stated, it is possible to maintain a uniform impedance over a wider frequency band by increasing the diameter of the antenna elements. This increase in diameter reduces the Q of the resonant system and this in turn causes a reduction in the reactive energy stored in the E and H fields adjacent to the antenna.

A cone antenna is a good example of increasing the diameter in order to obtain wideband operation. The bandwidth of this type antenna can be further increased by the use of compensating reactances. By the use of these series and shunt reactances, it is possible to increase the operating frequency range of the antenna as much as six times.

Figure 11-28 (B) and (C) show two cone type high frequency antennas for use with ECM equipment. In each of these, the electrical connections are brought to a receptacle at the bottom of the antenna. The antenna flange is designed to be mounted flush with the skin of the aircraft. A Plexiglass dome or blister is used to cover the antenna in order to afford protection and to reduce wind resistance.

The antenna illustrated in (B) should be mounted vertically to receive vertically polarized waves and horizontally to receive horizontally polarized waves. The antenna in (C) is similarly constructed except that the conical pickup element is mounted at an angle of 45° to the mounting flange. This permits reception of either horizontally or vertically polarized waves for a single mounting position.

Some antennas of this type have a high-pass filter incorporated in their assembly to attenuate all frequencies below their designed operating range. Signals below the operating range are filtered out and do not reach the equipment. It is important when selecting antennas of this type (especially for ECM equipment) that a close check be made, since an antenna that is equipped with this type filter will pick up a negligible amount of energy below its operating range.

CYLINDRICAL. — A modified cone antenna is shown in figure 11-28 (D). This assembly consists of a cylindrical antenna with an inverted cone shaped base fitted into a mounting flange. It is designed as a jamming transmitter antenna and covers the frequency range of 200 to 550 megacycles.

DIAMOND. — Another variation of the cone antenna is illustrated in figure 11-28 (E). It is a flat, diamond shaped metal plate enclosed in a streamlined plastic housing and is omnidirectional.

An antenna of this type, when operated at about 1,000 megacycles, will provide efficient operation over a bandwidth of approximately 200 megacycles. Since this antenna is made of a flat piece of metal, it may be mounted in an airfoil type plastic housing that offers little wind resistance. This is especially desirable for high speed aircraft.

The radiator is made diamond shaped, in order to obtain broadband frequency characteristics, and is vertically polarized. Since it is end fed, its impedance is comparatively high (140 ohms) and a matching section of transmission line is used to match this impedance to the 51 ohm transmission line. This section, which is a three-quarter-wave line, properly matches the impedances of the antenna and the antenna cable, and provides a low standing wave ratio along the cable. The antenna requires no adjustment.

Polyrod Antenna

Figure 11-29 shows a polyrod antenna that consists of a slender, tapered rod of special plastic. This rod is cemented to a piece of standard waveguide that is flared to match the square dimension of the large end of the rod. The principal mechanical features of this antenna are its streamlined aspect, its small size, and light weight.

95[illegible]

Figure 11-29. —A polyrod antenna.

It can be shown experimentally that very high frequency radio energy can be made to travel along a rod made of material having good dielectric properties in much the same way as light travels along a lucite rod. Some of the light traveling along the lucite rod is emitted from its longitudinal surfaces. Similarly, some of the radiofrequency energy traveling along the dielectric rod is radiated from its longitudinal surfaces.

By appropriately tapering the rod, the amount of energy radiated per unit length may be made approximately the same throughout the length of the rod. In doing so, an end-fire antenna is created which is roughly analogous to a linear array of dipoles spaced a quarter wavelength apart and fed at successive 90° intervals. For such an antenna array, the net energy radiated broadside to the rod will be a minimum. The rod, as seen from a point in a forward direction, will appear to be radiating a cigar shaped beam of energy.

HORN ANTENNA

The horn antenna provides a method of matching the impedance of waveguides to free space, and at the same time providing desired beam characteristics. Normally, the radiation pattern of an open-ended waveguide is broad in both the vertical and the horizontal planes. It is also an inefficient radiator system because of the mismatch between the waveguide antenna and free space. The evolution of the horn came about as a result of the effort to minimize the reflections that occur when a straight piece of waveguide radiates into space. By flaring the open end of the waveguide, the RF energy in the guide does not encounter such an abrupt impedance change when it reaches the end of the guide; hence, reflections and standing waves are minimized.

If the waveguide is flared out at a gradual angle, a horn antenna is obtained. The flare must be gradual so as to permit a better match between antenna and free space. At the same time, a sharper beam is obtained when a flared horn is used.

The horn is very practical at microwave frequencies since at these frequencies its physical size is not prohibitive. Since a resonant element is not involved, this type antenna is capable of wideband operation. Horn antennas used in aircraft installations produce beam patterns that are not highly directive. In order to produce a highly directive beam at lower frequencies, the antenna would have to be longer than practical for aircraft.

The horn antenna may be used with either circular or rectangular waveguides, and the same general considerations will apply: the longer the flare of the horn, the higher the gain and the narrower the beam width. For both circular and rectangular horns, the flare angle for the narrowest beam is between 40° and 60°. Generally speaking, the gain of a horn is less than that of a parabolic antenna. In order for the horn to have the same gain as a parabolic antenna, the horn must be much longer, which soon proves to be a big disadvantage.

A sectoral type horn antenna is illustrated in figure 11-30 (A). Its field distribution is spherical in shape and depends upon the mode of operation of the waveguide feeding it and the flare angle of the horn. The spherical shape of the wavefront becomes flatter (elliptical) as the flare angle of the horn decreases. This horn has the greatest degree of directivity in the plane of the widest dimension.

Two other types of horns to which the principles just described apply are shown in (B) and (C). The pyramidal horn (B) has equal directivity in both the vertical and horizontal plane.

Figure 11-30.—Horn antennas.

The conical horn (C) produces a conical beam pattern.

For horn antennas (as well as for dipole arrays and reflectors), a rule that may be kept in mind is that the larger the aperture of the waveguide or the larger the area of the array, the greater will be the gain and directivity. Since a large aperture is desired at the mouth, the length of the horn may become unwieldy if the gradual flare requirement is to be incorporated in the design.

However, a recent development in antenna design has made possible the use of horn antennas having a much larger equivalent size than was formerly practicable. This new type antenna has been called the JELLY-ROLL ANTENNA, due to its configuration. Effectively, it is the same as a conventional horn antenna rolled from the feed end toward the aperture end like a jelly roll. The resulting cylindrical shape uses less space than the conventional horn with the same size feed, the same angle of flare, and the same size aperture. Therefore, this saving in size could be used to good advantage by increasing the size of the aperture, with the resultant increase in directivity and gain.

Another method of improving the directivity and gain of a horn antenna is by the use of electromagnetic lenses to focus the beam in much the same manner that the light beams are focused by an optical lens.

MICROWAVE LENSES

A lens is a structure substantially transparent to microwaves, but which inserts a phase change over the cross section of the exit side of the lens to make the microwaves coverage or diverge. The lens is placed in front of a point source of RF energy, such as a feedhorn. The feedhorn is located at the focal point of the lens, and radiates spherical waves which are concentrated into a beam as they pass through the lens.

The focusing action of the lens is due to its ability to take the spherical wavefront of the energy transmitted by the horn and transform it into a plane wavefront. This is accomplished by changing the velocity of portions of the wavefront producing a flat wavefront. A wavefront that is flat will possess extremely good directivity. The lens may be made of plastic or it may consist of conducting strips of metal.

The explanation of microwave lenses can be better understood if we first consider a little background information. Then we will see that the microwave lens and its principles of operation are not strangers to us. Microwaves are similar to light in that both (like many other types of energy) travel in waveform. Consequently, both obey the physical laws of wave transmission. Although the primary purpose of an RF transmission line is to guide the transfer of energy from one place to another, in so doing the transmission line has other characteristics which may be useful in certain cases. For example, if a voltage is applied to the input terminals of a line, a definite amount of time passes before the voltage appears at the output terminal. In other words, the line has the ability to delay the transmission of voltages and currents. The time delay

is determined by the length of the line and its characteristics, R, L, and C. The time delay of a transmission line has many applications in radar timing. The artificial transmission lines used in radar employ this factor.

However, there is nothing in the physical laws of microwave transmission that says we must have a material conductor. The same laws apply to propagation of RF waves in air or in a vacuum. The velocity of wave propagation is determined by the characteristics of the medium through which it travels.

Microwave lenses are of two basic types. One type is the waveguide, or conducting type, shown in figure 11-31 (A). The other type is the dielectric, or delay type shown in figure 11-31 (C).

A sectoral horn with a conducting-strip lens is shown in figure 11-31 (A). This type accelerates wave transmission as it passes through the lens. It consists of flat metal strips placed parallel to the electric field of the wave and spaced slightly in excess of one-half of a wavelength. To the wave these strips look like waveguides with each hypothetical waveguide having a dimension in a direction perpendicular to the electric field corresponding to the spacing between the parallel strips. The velocity of phase propagation of a wave is greater in a waveguide than in air.

As you can see, the strips near the sides of the horn form longer sections of waveguide than those in the center. Since the lens is effectively concave (B), the phase velocity is progressively increased from the center of the

Figure 11-31.—Microwave lenses.

962

horn toward the sides as the lengths of the individual waveguide sections increase. The outer portions of the transmitted spherical wavefront are accelerated for a longer period of time than the inner portion. Therefore, this wavefront will emerge at the exit side of the lens aperture as a flat-fronted wave. This waveguide type lens is frequency sensitive (because of the change in phase velocity of waves in a waveguide with a change in frequency), so frequency stability of the transmitter is an important consideration in equipments where it is to be used.

A dielectric or delay type lens is shown in (C) of the figure. The delay lens, as its name implies, slows down the phase propagation as the wave passes through the lens. This lens is convex, and consists of dielectric material. The delay in the phase of the wave passing through the lens is determined by the dielectric constant (or refractive index) of the material. In this case, the inner portion of the transmitted wave is decelerated for a longer interval of time than the outer portions. (See fig. 11-31 (D).)

Many lenses of this type use artificial dielectrics consisting of conducting rods or spheres that are small compared to the wavelength. Artificial dielectrics, or conducting insulators, are covered in Basic Electronics, NavPers 10087-B.

In a lens antenna the exit side of the lens can be regarded as an aperture across which there is a field distribution. This field acts as a source of radiation just as fields across the mouth of a reflector or horn. For a returning echo the reverse effects take place in the lens.

It can be seen that the reflector uses the law of reflection while the lens uses the law of refraction. The rear feed arrangement of the lens antenna eliminates spillover radiation in the backward direction. Also, this arrangement puts the radiator out of the path of the beam, thus reducing shadows.

The plastic type lens, shown in figure 11-31 (C), is affixed to a conical horn type antenna. This particular antenna produces a beam width of 18° at half-power points and has a gain of approximately 100. The lens is effective in reducing the sidelobe intensity by retarding the phase of the energy leaving through the center of the lens. This causes the energy to leave the horn in a plane of constant phase.

While the two types of lens produce the same results they operate in somewhat opposite manner. The plastic lens retards the phase of the energy at the center and the conducting-strip lens accelerates the phase of the energy at the edge.

It is interesting to compared the characteristics of this antenna with those of the polyrod shown in figure 11-29. While the half-power beam width of the horn is 18°, that of the polyrod is 25°. However, the spurious radiation from the polyrod is of greater magnitude than that from the horn. These factors cause the polyrod to be less efficient than the horn, but nevertheless, in some applications, it is more desirable because of its mechanical features.

MONOPULSE ANTENNA

The methods of radar scanning covered in Basic Electronics (NavPers 10087-B) and Aviation Electronics Technician 3 & 2 (NavPers 10317-C) are sometimes called sequential lobing, because target information must be gathered from a series or sequence of pulses. The high speed response and fine degree of accuracy required of tracking radars in modern high speed weapons systems have made this system unsuitable for some applications. Another scanning technique, called MONOPULSE or simultaneous lobing, can obtain information on target range, bearing, and elevation from a single pulse. This system is presently used in some of the newer type fire control and tracking radars.

For target tracking, the radar discussed here produces a narrow circular beam of pulsed RF energy at a high pulse repetition rate. Each pulse effectively is divided into four signals which are equal in amplitude and phase. The four signals are radiated at the same time from the four feedhorns as indicated in figure 11-32.

The radiated energy is focused into a narrow beam by a microwave lens. Energy reflected from the target is refocused by the lens into the feedhorns. The total amount of energy received by each feedhorn is determined by the position of the target with respect to the center of the beam. This is illustrated for four targets at different positions with respect to the beam axis. Notice that a phase inversion takes place at the microwave lens similar to the image inversion in an optical system.

Figure 11-32.—Monopulse technique.

The amplitude of returned signals received by each horn is continuously compared with those received in the other horns, and error signals are generated which indicate the relative position of the target with respect to the axis of the beam. Angle servocircuits may be used to receive these error signals and correct the position of the radar beam to keep the beam axis on target.

The BEARING (azimuth) signal is made up of signals from horns 1 and 3 (added)and from horns 2 and 4 (added). By waveguide design the sum of 2 and 4 is made to have a 180° phase relation with the sum of 1 and 3. These two sums are combined, and the bearing signal is the difference of (1+3) — (2+4). Since the horns are positioned as shown in the figures, the relative magnitudes of the horn signals give an indication of the bearing error.

The ELEVATION signal consists of the signals from horns 3 and 4 added (with 180° phasing) to 1 and 2; i.e., (1+2) — (3+4) (The 180° phasing accounts for the negative sign.)

The RANGE (sum) signal is composed of signals from all four feedhorns addedtogether in phase. This range signal is also used as a reference signal for the bearing and elevation error signals. The bearing and elevation error signals are compared in the radar receiver with the reference (range) signal. The output of the receiver may be positive or negative pulses, depending on direction of error, with a magnitude proportional to the angle between the boresight (beam) axis and a line drawn to the target. Of course, if the target is directly on the boresight line, the output of the receiver is zero, and no angle tracking error is produced.

In the monopulse system, certain problems are inherent, and suitable provision must be made for their solution. Among the most important of these problems are:

1. A single magnetron output must be fed to all four antenna feedhorns, and these must be in phase and of equal magnitude.

2. Echo signals received by the feedhorns must be fed to the receiver channels with the proper phasing and magnitude.

3. Range (reference) signals are to consist of the echoes from all four horns, added in phase.

4. Elevation angle error signals must reflect the difference in magnitude and the polarity of the difference in the sums of the signals from horns 1 and 2 and from honrs 3 and 4, added in phase.

964 [illegible]

5. Bearing angle reference signals must reflect the difference in magnitude and the resulting polarity of the sums of the echoes from horns 1 and 3 and from horns 2 and 4, added in phase.

These problems are solved in part by the use of the MAGIC-T COUPLER.

Magic-T Coupler

As shown in figure 11-33 (A), a magic-T coupler consists of four energy paths with a common junction. For the following discussion, assume that the magnetron's output is fed through a TR/ATR duplexer to path 3, and that the return echo signals present in path 3 are fed through the same duplexer system to a reference channel in the receiver. Further assume that paths 1 and 2 are fed to two of the antenna feedhorns, and that path 4 is fed into another channel of the receiver (either elevation or bearing).

Transmitted energy in path 3 (fig. 11-33 (A)) is propagated in equal amounts in paths 1 and 2. None is propagated in path 4 since no field strength difference exists across its face (which is at right angles to the transverse electric mode). Target returns appearing at paths 1 and 2 in equal field strengths are therefore propagated in path 3 but not in path 4 since, again, no field strength difference exists across its face. However, if the received signals appearing at paths 1 and 2 are not of equal field strength, a potential difference does exist across the face of path 4, and energy is propagated into this waveguide in an amount proportional to the difference in field strengths between paths 1 and 2; that is, a potential difference must occur across the face of path 4 in order for energy to be propagated in this path. A potential difference will occur across the face of path 4 when there is an imbalance between the signal strength from path 1 and path 2. The amount of energy propagation in path 4 is dependent upon the magnitude of this imbalance in signal strength between path 1 and path 2.

Figure 11-33. —Magic-T coupler, basic drawings.

If there is energy propagated in path 4, its phase relationship to the reference (sum) signal is determined from which path (1 or 2) the greatest signal is supplied and by the construction of the magic-T coupler.

In airborne radar systems, it is frequently necessary to develop an error signal in only one geometric plane — either bearing or elevation. Figure 11-33 (B) illustrates the principle applied in one typical height finding (elevation) application. Note that a single horn radiator is used to effectively produce both the up and the down signals. Although there is no physical surface separating the paths 1 and

965 036

2, the positioning of the magic-T slot (path 3) along the boresight axis of the feedhorn effectively divides the horn into two identical halves.

The feedhorn effectively comprises two functional antenna sections — one for the sum channel (Σ guide) and one for the difference channel (Δ guide). Note, however, that only the sum channel (path 3) is used for transmission.

The primary receiving channel is the sum waveguide and feedhorn combination. The horn is an impedance matching device used to propagate the transmitter output pulses into the atmosphere (and to shape the pattern radiated against the reflector). Echoes reflected from the targets enter the open end of the feedhorn as a single receiving pattern, and are propagated through the waveguide to produce the sum video signals. The secondary receiving element is the difference channel (Δ guide) and consists of the magic-T slot (path 4) which is incorporated into the horn configuration.

Each half of the horn is effectively a separate waveguide (or receiving antenna) having its own sensitivity pattern. When the target is situated along the boresight axis of the antenna, equal sensitivities exist for paths 1 and 2, so no difference signals are propagated. For targets above the boresight, the upper half of the antenna is somewhat more sensitive to echoes than the lower half, and will respond with a stronger signal than the lower. This results in a difference in field strength between the signals in paths 1 and 2 of the magic-tee.

Because of the difference in these field strengths, a potential difference exists across the Magic-T slot (path 4), and a small amount of energy is propagated in the guide. The amount of energy so propagated is directly related to the difference of the field strengths in the input arms.

When a target is located below the boresight axis of the feedhorn, the lower half of the antenna is more sensitive to radar echoes than the upper half.

The phase relation of the difference and sum signals is determined by the physical position of the magic-tee slot with respect to the opening into the sum channel waveguide. The antenna configuration is chosen so that a difference signal, which is caused by greater energy in one channel, is in phase with the sum channel reception, while the reverse energy condition results in the opposite phase. Only a small portion of the total received energy is coupled to the difference channel; the major portion is propagated in the sum channel, and is used as the target display in the indicator.

There are numerous variations of nonpulse radar systems in use in naval airborne electronics applications. For specific details on the peculiarities of an actual type equipment, consult the applicable Maintenance/Service Instructions manual for that equipment or aircraft.

CHAPTER 12

UHF AND MICROWAVE TECHNIQUES

The increase in congestion of the communication channels below 30 mc and the special advantages of the shorter wavelengths in the very high and ultrahigh frequency bands have led to increasing use of these parts of the RF spectrum.

The upper limit for radio signals that can be returned effectively to the surface of the earth by the ionosphere is about 30 mc. Therefore, 30 mc was chosen as the low frequency limit of the VHF band. This 30-mc dividing line is not an abrupt one, because there is no abrupt change in the avility of the ionosphere to return the waves to earth as the frequency is increased. The change of behavior of the ionosphere takes place over a region of the frequency spectrum with its center at about 30 mc. The band of frequencies in which the ionosphere behavior changes may occasionally move higher or lower by considerable amounts.

The 300-mc dividing line between the VHF and UHF bands and the 3,000-mc upper limit of the UHF band likewise are more or less arbitrary and are agreed upon for convenience. Again, these dividing lines are not abrupt. The limits should be thought of as transition regions, centering on those frequencies.

Communication equipments below 225 mc in the VHF range are not used extensively any more, because most tactical voice circuits now operate in the UHF band. Limited installations of VHF equipment are retained, principally for communication with allied forces who have not yet converted to UHF equipments.

Transmitters and receivers installed in naval aircraft cover only parts of the VHF and UHF bands. VHF equipments cover the range of frequencies from 115 to 156 mc. UHF transmitters and receivers are designed for 225- to 400-mc operation. Although this frequency range includes the upper portion of the VHF band, the equipments are commonly referred to as UHF equipments.

It must be understood that the behavior of radio waves at VHF, UHF, and microwave frequencies is very different from their behavior at lower frequencies, and the differences are extremely important. For this reason, this chapter begins with information on the fundamental differences of radio waves in this frequency range and the reasons for the differences.

The distributed properties of inductance, capacitance, and resistance associated with any conductors are discussed first, because their effects must be understood before the action of electronic circuits at these frequencies can be comprehended. In particular, the effects of these distributed properties in the connecting leads in electronic circuits are presented. These effects comprise the principal reason for the physical differences between equipment operating in this frequency range and the more familiar circuits used at lower frequencies.

It is also necessary to understand the changes that occur in the behavior of lumped-property components, such as inductors, capacitors, and resistors, when they are operated in the VHF/UHF/microwave region. The differences in design of components meant for operation in these frequency bands are compared with the more familiar lower frequency components.

The purpose of this chapter is to acquaint the AT with oscillators and amplifier circuits employed at UHF and microwave frequencies. Also, information dealing with the pulsing techniques used in RF generators of this frequency range is presented. Specifically, it discusses problems involved in generating high frequency signals, explains the theory and operation of a number of oscillators, amplifiers, and other microwave circuits employed at these frequencies, and describes various methods for pulsing oscillators.

967 838

ADVANTAGES OF USING HIGH FREQUENCIES

At 30 mc and above, the ionosphere does not return radio waves to the surface of the earth very effectively, except under rather unusual conditions. This limits the effective range of radio communication and radar coverage in these frequency bands to points not far beyond the optical horizon as seen from the transmitting antenna. At first this was considered a serious limitation because most of the emphasis was on long distance communication, far beyond the horizon. It soon was realized, however, that the shorter wavelengths could be used for covering relatively local areas. This made some additional lower frequencies available for long distance communication.

Because propagation of these shorter radio waves does not reach points on the surface of the earth beyond the horizon, stations can operate on the same assigned frequency without interference, if they are separated far enough geographically. This provides reliable short range communication and is widely used in naval operations at sea, for convoy communications, for communication between ships and aircraft, and for communications between aircraft.

A second effect of the decrease in wavelength as the frequency is increased is related to the phenomenon of radio wave reflection. All electromagnetic waves, such as radio, light, and infrared radiation, can be reflected but how well they are reflected depends on a number of different factors. One factor is the relationship between the length of the wave and the physical size of the reflecting object. The AT needs to concern himself with this phenomenon because it is one of the basic principles on which radar operates, and its importance can hardly be exaggerated.

Another factor directly related to wavelength is the physical size of the equipment used to generate the RF energy, and the antenna needed to radiate it effectively. Both of these factors can be made smaller in direct proportion as the wavelength is made shorter. Obviously, equipment for the shorter wavelengths can be made smaller and more compact because of this relationship between physical size and wavelength.

Aside from the factors of size and weight, these frequencies are highly applicable to radar equipment for they produce better target echoes and make possible the detection of smaller targets. The size of the target that radar can detect depends mostly on the frequency. In general the higher the frequency, the smaller the target that the radar can detect. A target gives the best echoes when its size is about one-half the wavelength (or some multiple on the wavelength) at the frequency being transmitted. If the target is much smaller than a wavelength, the intensity of pulse that it reflects is low. However, as the operating frequency is increased, the wavelength becomes smaller making it possible to detect smaller targets.

DISTRIBUTED PROPERTIES

Distributed properties may be defined as the inductance, capacitance, and resistance uniformly spread along each unit length of any circuit element, plus the inductance, capacitance, and resistance existing from each conductor to ground and to other objects. For example, a 1/4-inch rod of copper, 4 inches long, placed in free space where no outside influence could act upon it, would be found to possess small but definite values of inductance, capacitance, and resistance. If the conductor were cut in half, each part would possess exactly half the values previously found. In other words, the distributed properties are uniform as long as the conductor itself remains uniform in cross sectional size, shape, and conductivity, provided that no external influences exist. If the conductor is not uniform, the distributed properties still exist, but their distribution is not uniform.

When a conductor is placed in an actual circuit, it possesses these self-contained distributed properties, and may or may not possess additional distributed properties caused by its proximity to ground and to other components in the circuit. Distributed properties exist in all conductors and conducting surfaces, even in the leads and other parts of the lumped-property circuit elements (capacitors, coils, resistors), which are manufactured to provide definite amounts of the properties. When used in practical circuits at VHF/UHF/microwave frequencies, however, the distributed properties of inductance, capacitance, and resistance in a given conductor actually are not fixed amounts or constants, but slowly change in value as the frequency changes.

At frequencies below 30 mc it is practicable to ignore distributed, or stray, circuit properties, except in circuits such as resonant sections of transmission lines or antennas. Above 30 mc, the effects of distributed properties upon practical circuits can no longer be neglected, because of the relationship between the physical size of the circuit components and the wavelengths. At 3 mc, for instance, one wavelength is 100 meters long, in comparison with which a 6-inch length of wire is very short. When the wavelengths become relatively short, as the frequency increases, it becomes physically impossible to scale down the parts of the electronic circuit and keep them small in relationship to wavelength. Even where such a size reduction is possible, the power handling ability of the circuit is reduced in proportion. As a result, much of the usefulness of the device is lost.

When the operating frequency increases, the various losses that reduce circuit efficiency increase, making it desirable to use circuit arrangements and elements that have lower built-in losses. So far it has been found impossible to construct lumped-property elements that are pure and do not contain small distributed values of the other two properties. As the working frequency increases, the effects of the unwanted distributed properties cause increased losses, with the result that the efficiency drops. In circuits utilizing distributed properties, losses are lower than in the same circuits constructed of lumped-property elements, because it is possible to use conductors of proper size and shape to minimize RF resistance and because the dielectric is usually air. The result is that better circuit stability and efficiency are achieved by using the distributed properties.

Distributed Inductance

The term "distributed inductance" refers to the self-inductance distributed along the length of any type of conductor, whether it is or is not meant to act as in inductor. Inductance, as defined in Basic Electricity, NavPers 10086-A, is the property of a conductor that tends to oppose any change of electron flow (current) through the conductor. Inductance reveals itself only when current is varying in the conductor; a back emf (electromotive force) is induced in a direction that tends to oppose the change in current flow. It is apparent that even a very short section of straight wire possesses self-inductance. The conductor does not have to be wire, however; it can be any conductor, any shape or size.

Usually, the actual amount of self-inductance is small, but its effect becomes important at frequencies above 30 mc. The effect may be desirable or unwanted, but it cannot be ignored. A complex equation is needed to find the actual value of self-inductance, but the important point here is that the value depends directly on the number of lines of flux surrounding the conductor. Self-inductance is highest at the center of any conductor carrying alternating current, and tapers off toward the outside surface. This is the cause of skin effect, explained later.

UNDESIRABLE EFFECTS.—The property of distributed inductance can cause serious RF losses if leads and connecting linkages are not kept as short as possible. Figure 12-1 demonstrates how this loss takes place. The plate tank circuit (A) is designed to operate at a frequency of 4 mc. The inductor is connected to the tube plate by a wire having a self-inductance of approximately 0.1 microhenry (μh).

Figure 12-1.—Effect of distributed inductance at higher frequencies.

969

Ignoring loading and other factors; calculation shows that the resistive impedance offered by the tank circuit at resonance is 4,710 ohms, where the inductive reactance ($X_L = 2\pi fL$) of the connecting wire is approximately 2 ohms, and is so small in proportion to 4,710 ohms that it can be neglected at this low frequency.

When the operating frequency is raised to 100 mc (fig. 12-1 (B)), the inductance of the tank coil must be reduced to resonate at the higher frequency. At 100 mc, the self-inductance has decreased slightly but the increase in frequency raises the inductive reactance of the plate lead to 59.6 ohms. The resistive impedance of the of the tank circuit is still 4,710 ohms at resonance. A voltage divider effect occurs, which prevents the entire RF signal output of the tube from being impressed across the tank circuit and results in a loss of gain. In addition, the introduction of an inductive component causes a phase lag that is undesirable in certain applications. At higher frequencies, the effect becomes even more pronounced, introducing larger losses.

DESIRABLE EFFECTS. —In certain circuits, a condition of series or parallel resonance is desired, and the property of distributed inductance, distributed capacitance, or a combination of both, may be used to achieve this. For example, to provide a bypass for signal voltages from the low-impedance end of an IF tank circuit back to the cathode of the tube, a series resonant circuit offers the lowest impedance path. When the IF frequency is above 30 mc, it is possible to get the effect of series resonance by cutting the leads of the capacitor to lengths offering the necessary series inductance. This is shown in figure 12-2 (A). Note that the capacitance is lumped, but the inductance is the distributed inductance of the capacitor leads. (See fig. 12-2 (B).) However, the signal voltage sees a certain value of each property, regardless of whether the properties are lumped, distributed, or any combination thereof.

Figure 12-2. —Series resonance; lumped capacitance and distributed inductance.

INDUCTIVE COUPLING. —When a conductor carrying alternating current runs sufficiently close to another conductor, its magnetic field induces an electromotive force in the second conductor, causing a current to flow. This is the effect of mutual inductance.

The study of mutual inductance and coupling at lower frequencies usually is restricted to coils and transformers, but above 30 mc the effect of coupling between two conductors—even two straight pieces of wire—becomes important. This is true because the amount of coupling or mutual reactance between two inductors increases as the frequency is increased, if the physical relationship remains the same.

970

Some effects of coupling between distributed inductances are undesirable. For instance, if the grid and plate leads of a single-tube amplifier stage are permitted to run close to each other, signal energy from the plate circuit may be coupled back to the grid, causing either regeneration or degeneration. Distributed capacitance also is present, but only the inductive coupling effect is considered at this time. As another example, a current carrying wire may be too near a tube shield, inducing an emf that causes current to flow in the shield. This current flow through the shield is a power loss that can be supplied only from the current carrying wire.

When inductive coupling causes circuit imbalance or power loss, it usually is spoken of as stray coupling. The amount or degree of coupling depends directly on the relative positions of the conductors as well as their distance from each other. Figure 12-3 shows the effect of physical position on the degree of coupling. In (A) the coupling is loose, inasmuch as the leads are crossing at right angles, and the least mutual inductance results. The coupling between the wires (B) and (C) increases because of the greater amount of mutual inductance. Practical circuits are laid out with the shortest possible leads, well separated from one another and distance from the chassis and shields. If two wires must cross, they should cross at right angles, because in this manner the smallest mutual inductance results.

Figure 12-3.—Inductive coupling effects at higher frequencies.

Distributed Capacitance

The term "distributed capacitance" refers to the capacitance between any point on a conductor and all surrounding objects. Capacitance exists between any two points that are at different electrical potentials. This is true whether the points of different potential are in different conductors or in the same conductor. Although the self-capacitance of a conductor is of relatively little importance, except in special circuits, the effect of the capacitance between two conductors must be taken into consideration at VHF/UHF/microwave frequencies. This is because of the distributed capacitance that exists between the parts of circuit elements and the electrodes of electron tubes. as well as between leads and switch contacts.

The actual value of distributed capacitance changes only slightly with frequency, but the reastance changes greatly. The formula for capacitive reactance ($X_C = \frac{1}{2\pi fC}$) shows that, if the value of capacitance remains the same, increasing the frequency causes the capacitive

reactance to decrease. Therefore, a small value of distributed capacitance at the lower frequencies offers a high reactance to the flow of a.c., but at higher frequencies it offers a lower reactance. This effect often is undesirable when it occurs accidentally between two conductors in a circuit, but may be used deliberately to achieve series or parallel resonance in resonant line sections. The losses in distributed capacitance are lower than those in lumped capacitors because the dielectric is usually air, instead of a solid, and because the RF resistance and distributed inductance values are smaller.

UNDESIRABLE EFFECTS.—An example of the manner in which distributed capacitance may upset the proper operation of a circuit is shown in figure 12-4.

Assume that C_d represents a distributed, or stray, capacitance of 1$\mu\mu$f appearing between ground and the lead from the coupling capacitor to the grid of tube V2. The stray capacitance C_d effectively shunts the 5,000-ohm grid impedance Z_g. If an RF signal at a frequency of 2 mc is traveling from the tank circuit of V1 to the grid of V2, the 1$\mu\mu$f distributed capacitance offers a capacitive reactance of 79,618 ohms to the signal. This value is so high in relation to Z_g that its effect is negligible at this frequency and similar low frequencies. If, however, a 100-mc signal voltage is coming from the tank circuit of V1, the same 1-$\mu\mu$f stray capacitance offers only 1,592 ohms of capacitive reactance.

Figure 12-4.—Effect of distributed capacitance at higher frequencies.

Now the signal voltage sees a relatively low impedance path across the stray capacitance, offering less than one-third the opposition of the grid impedance Z_g. Therefore, more than two-thirds of the signal voltage is shunted across this path and lost. If the frequency of the signal voltage is increased to 400 mc, the reactance drops to 398 ohms, and only a very small amount of the signal voltage reaches the grid impedance.

To keep the stray capacitance at a minimum, the circuit wiring is kept well spaced with short leads that run at right angles to one another whenever possible.

DESIRABLE EFFECTS.—For certain applications, such as IF amplification, a parallel LC (inductance-capacitance) circuit, resonant at a single frequency, is useful. A simple way of achieving this is to wind a coil in such a manner that the total distributed capacitance is used to make the coil self-resonant at the desired frequency.

Part (A) of figure 12-5 shows the distributed capacitance that exists because of the difference of potential between adjacent turns of any coil. The sum of these small values is shown in part (B) as an effective value of capacitance in parallel with the lumped inductance of the coil. Although most inductors are wound to minimize the distributed capacitance, some are designed to offer the necessary capacitance to provide a desired L/C ratio. This offers an advantage because the response of the tuned circuit can be made sharper than would be possible with lumped-property coils and capacitors.

Distributed Resistance

The term "distributed resistance" seldom is used, because it is necessary to distinguish between the resistance offered to d.c. and low-frequency a.c. and the resistance offered to RF currents at the higher frequencies.

Depending on the conductivity of the metal or alloy, all conductors have d-c resistance. It is distributed uniformly along conductors that are uniform in cross sectional area, shape, and conductivity. Resistance to RF, however, is caused by d-c resistance plus the effect of self-inductance, which is greater at the center of a conductor than at the surface. At the lower frequencies, this self-inductance has little effect on the flow of current because the values of inductive reactance are extremely small.

972

Figure 12-5.—Parallel resonance; lumped inductance and distributed capacitance.

As the operating frequency increases, the inductive reactance at the center of the conductor becomes higher, and the current seeks the lower reactance path toward the surface, resulting in a current distribution that is not uniform.

This tendency of the current to flow on or near the surface of a conductor is called SKIN EFFECT. As the frequency increases, less current flows in the center of the conductor and more flows on the surface. The result is that more current is forced through less conductor material, with higher losses and more heating. Because the center of the conductor is not carrying current, the effect is the same as using a smaller conductor. The RF resistance at higher frequencies can amount to several times the d-c resistance of the same conductor.

MINIMIZING SKIN EFFECT.—Skin effect takes place regardless of the shape of the conductor, but it causes less RF resistance in conductors having rectangular cross sections than in those that are circular. Flat copper strips are sometimes used, but are more expensive and not easy to work.

Litz wire, as it commonly is called, is made up of many strands of very fine enameled wire woven together. The current is divided among the strands, and the skin effect on any single conductor is extremely small. Litz wire is comparatively expensive, however, and is not widely used.

Probably the best method of avoiding losses from RF resistance is by silver plating the conductors. This does not eliminate skin effect, but takes advantage of it. When the plated conductor carries RF current, skin effect takes place as usual. Now, however, the current is flowing in the silver plating, which has less d-c resistance than ordinary conductors; therefore, the RF resistance is reduced considerably. In practice, plating is expensive, limiting its use.

The most common means of reducing RF resistance is to use a hollow conductor or one of larger diameter. Again, this does not eliminate skin effect. The depth to which the current penetrates is affected only by the frequency and the conductor material; consequently, when the diameter is increased, the current layer has the same thickness but more cross sectional area in which to flow. This reduces the effective RF resistance.

LUMPED-PROPERTY COMPONENTS

A lumped-property component is an electronic part in which a definite amount of capacitance, inductance, or resistance exists, usually with relatively little of either or the other properties present. Capacitors, coils, and resistors used in radio equipment operating at frequencies below 30 mc generally a lumped-property components.

As the frequency of operation is raised, the electrical loss in lumped-property components increases, until a frequency is reached where this increasing loss cannot be tolerated. The increased loss is actually a combination of three distinct effects—dielectric loss, RF resistance loss, and radiation loss.

Loss in even the best dielectric materials increases with frequency, because a definite amount of applied electrical energy is lost in each cycle, and the more cycles that occur in a unit of time, the more heat is generated in the dielectric.

The RF resistance loss also increases with increasing frequency, because of skin effect.

Radiation loss occurs in any RF circuit because of direct radiation from the parts. This loss is usually negligible, so long as the circuit is not more than about one-tenth of a wavelength in any physical dimension. With increasing frequency, however, it becomes impossible to scale the components down in physical size in proportion to the decreasing wavelength, and radiation losses increase. The addition of RF shielding around the circuit also causes energy to be lost in heating the shield, rather than by radiation.

Capacitors

All capacitors, of any size, type, or construction, have characteristics that cause them to behave in a way unlike the theoretical ideal capacitor, which would have pure capacitance, and no inductance or resistance. Practical capacitors actually have some series inductance because of their leads and internal metallic foil plates. This inductance is effectively in series with the actual capacitance as shown in the approximate equivalent circuit of figure 12-6 (A) where C represents the actual capacitance, L the inductance of each lead, and R the effective RF series resistance of the leads and foils. Losses in the dielectric are represented by the shunt conductance, G. Below 10 mc, dielectric losses are seldom serious, even in ordinary paper capacitors, and in high quality mica and ceramic units it has no serious effects at the highest frequencies.

Since capacitors have a small (but significant) amount of inductance in series with the actual capacitance, there is a resonant frequency at which the reactances of the inductance and capacitance become equal, and cancel each other. The reactance becomes capacitive below series resonance, and grows larger as the frequency decreases. The opposite effect takes place above resonance, where the reactance is inductive, and grows larger with increasing frequency.

The common types of electrolytic, mica, paper, and ceramic capacitors are subject to increasing losses as the operating frequency is increased. In electrolytic capacitors, these losses and the inductance of the leads and internal foil strips that form the plates make them practically ineffective as capacitors at frequencies above a few megacycles. Even in equipment operating below 30 mc, electrolytic capacitors usually are shunted with a paper of mica capacitor of suitable value, which bypasses the higher frequency currents around the electrolytic unit.

Figure 12-6.—Equivalent high frequency circuits.

Paper capacitors also are subject to serious losses as the frequency is raised, but not to the same severe extent as in electrolytic units. The series inductance of paper units is large, and causes them to become series-resonant at frequencies ranging from 1 to 10 mc, depending on the capacitance and lead length.

Mica capacitors, because of their lower losses and smaller series inductance, have an extended range of usefulness. Average types become series-resonant at frequencies from 10 to 100 mc, depending on the capacitance value and lead length.

Ceramic capacitors are a more recent development and have improved properties in certain respects. Their losses are lower than those of mica units, and their design permits a much lower series inductance. As a result, their series resonance may be as high as 400 or 500 mc and this, together with their stability and low losses, makes them preferred in many VHF/UHF/microwave applications.

IMPROVEMENTS IN CAPACITORS.—Changes in the materials and design of capacitors have been made to adapt them for more effective performance at frequencies above 30 mc. In general, since capacitors do not behave as capacitors above their own resonant frequency, most of the improvements have been made with a view to raising the resonant frequency. The greatest improvement resulted from the development of ceramic materials that made possible ceramic-dielectric capacitors with only two plates, as compared with the many interleaved foils necessary in paper and mica units. Ceramics also made possible capacitors with various temperature coefficients which can be used to improve the stability of critical circuits.

Various ceramic materials, such as barium and strontium titanates, have been found to have high dielectric constants and good dielectric strength. By plating or firing silver electrodes directly on thin plates of this dielectric material, air and moisture are prevented from getting between the plates of the capacitor. This results in greatly improved stability. By varying the mixture of the ceramics, the temperature coefficient of the capacitor can be made negative, zero, or positive, as desired. Ceramic capacitors then can be used to compensate for frequency drift caused by changes in other components with changes in temperature. Skin effect is reduced by using short, heavy leads, and losses caused by surface leakage and humidity are minimized by sealing the surface with baked silicon lacquer. A similar process of plating or coating the silver electrode on mica also has been developed for the manufacture of mica capacitors, with considerable improvement in their stability and high-frequency performance.

Inductors

All inductors have some distributed capacitance between turns, which appears as a small capacitance in parallel with the external circuit. When the applied frequency is increased to a point where the distributed capacitance of the coil resonates with the inductance, a new effect appears. The coil becomes a parallel-resonant circuit (fig. 12-6 (B)) to the external circuit connected to its terminals. The resistance in this equivalent circuit represents the losses incurred in practical coils. This self-resonant characteristic is used in many applications in VHF/UHF/microwave receivers. The inductor is made to resonate with its own self-capacitance, plus the tube input and stray circuit capacitance. This eliminates the need for a separate tuning capacitor and provides the highest possible inductance-capacitance ratio, the largest load impedance, and the greatest stage gain.

Self-resonant inductors are often used in the IF amplifiers of communications receivers. If adjustable tuning is required, it is accomplished by varying the inductance either by a switching arrangement or with an adjustable core (slug) of plastic impregnated with iron powder.

In transmitter circuits, the inductor must handle considerable power without serious heating. This requires a coil of larger physical size, and usually makes the use of iron powder cores impractical because such cores tend to saturate magnetically and lose efficiency as the power level increases. Inductors in transmitter circuits thus are usually of the air wound, self-supporting type.

Resistors

The effects of increasing frequency on the performance of some types of resistors are such that the resistors cannot be used efficiently at frequencies of 30 mc and upward. Wire wound resistors that are used at low frequencies become useless above this range because of unavoidable inductance and capacitance, which introduce unwanted reactive or resonant effects. Therefore, composition resistors made of finely divided carbon in a suitable binder are most commonly used in this frequency range.

For practical purposes, the simple equivalent circuit shown in figure 12-6(C) illustrates the effective impedance of a composition resistor at high frequencies. This equivalent

975 [illegible]

circuit generally is used in the design of VHF, UHF, and microwave circuits. R_p is the reciprocal of the conductance and is referred to as the parallel resistance. The total effective capacitance, C, is caused by the capacitance between the leads and the distributed capacitance.

Resistors made by depositing a thin layer of pure, finely divided carbon or a carbon and boron mixture on the surface of a ceramic or glass tube provide improved performance characteristics at all frequencies. They are particularly stable, and they show less change in impedance with increasing frequency.

FREQUENCY LIMITATIONS OF CONVENTIONAL OSCILLATORS

The principal factors which limit the frequency of the ordinary type oscillator are the construction of the tube and the external circuits which connect to the tube.

Although the basic principles of vacuum tube operation are unchanged, certain factors that can be disregarded in tube operation below 30 mc become important at higher frequencies. The inductances of the electrode leads and the capacitances between electrodes are very small, but at higher frequencies their reactances become significant. In addition, electrons do not travel instantaneously from the cathode to the plate, but require a TRANSIT TIME. This causes an in-phase grid current to flow, even though the grid is negative, and results in a loading effect across the input that reduces overall gain in all classes of tube operation.

Skin effect in the electrodes and electrode leads causes the RF resistance to increase with frequency. Dielectric losses in the insulating electrode supports are increased, and some power is lost by direct radiation from the electrodes and their leads. The effect of these factors is to cause tube efficiency to become progressively lower as the operating frequency is increased. For example, a tube operated as an amplifier at 50 mc gives less output for a given signal input than at 5 mc, even if the external circuits are equally efficient at both frequencies. Also, because these losses increase with frequency, there is a practical upper frequency limit beyond which the tube is not useful as an amplifier. If the same tube is operated as an oscillator, the high frequency limit of operation will be about two-thirds to three-fourths that of the limit as an amplifier, because the tube no longer can supply sufficient output to make up the increased losses and still provide a useful output signal.

These effects are always present in a vacuum tube; no matter what the operating frequency. As the frequency is raised, the effects increase and become so large that they place an effective upper limit on useful operation. Although it is not necessary to learn new operating principles, it is important to understand how and why these characteristics that previously were disregarded become major limitations at frequencies above 30 mc.

TUBE CONSTRUCTION FACTORS

As the wavelength is made shorter, it becomes comparable in length to the physical length and spacing of tube electrodes and leads. The apparent solution to this difficulty is to scale down the entire tube structure. There is a practical limit, however, governed by the power handling capacity required. New tube designs have been developed that successfully overcome one or more of the limitations without requiring a drastic size reduction. For further details on tube design, review chapter 1 of Basic Electronics, NavPers 10087-B.

Interelectrode Capacitances

As has been pointed out in Basic Electronics, NavPers 10087-B, a small but significant value of capacitance must exist between any element of an electron tube and each of the other elements. Additional capacitances exist between the leads, particularly in those tubes in which the leads are brought out through a common stem to the base. When the tube is operating with normal voltages applied, the effective capacitances between electrodes are different from the capacitances when the cathode is not emitting. These differences are caused partly by expansion of the parts when the tube heats and partly by the electron stream.

When the tube is cold, the dielectric between electrodes is mostly vacuum, but in operation this vacuum is partially filled with a stream of electrons, resulting in a change in the dielectric constant. Naturally, this changes with variations in the electron stream. The normal capacitance values are measurable, and are listed in tube characteristics tables.

The discussion of interelectrode capacitance in Basic Electronics, NavPers 10087-B, establishes the relationship between operating frequency and capacitive reactance within electron tubes. A good point to remember is that the higher the frequency (or the larger the interelectrode capacitance) the higher the current flow through this capacitance. In most UHF oscillators employing ordinary tubes, interelectrode capacitance currents are much greater than the power currents supplied by the tube. These higher currents cause power losses in the resistance in the oscillatory circuit.

Since interelectrode capacitances are effectively in parallel with the tuned circuit, they affect the frequency at which the tuned circuit resonates. In the circuit illustrated in figure 12-7, the plate to cathode capacitance is in parallel with the series combination of the plate to grid capacitance and the grid to cathode capacitance. All these capacitances together form a part of the total capacitance of the plate's tuned circuit. Their total capacitance is calculated by the formula,

$$C_t = C + C_{pk} + \frac{C_{gk}\,C_{gp}}{C_{gk} + C_{gp}}$$

Not only does interelectrode capacitance limit the frequency by establishing a minimum value below which it is impossible to go, but it also varies with the applied voltages and with the loading of the oscillator. This causes frequency instability, particularly when the interelectrode capacitance forms a large part of the tuning capacitance.

Figure 12-7.—Effect of interelectrode capacitance on frequency of tuned plate, tuned grid oscillator.

Inductance of Leads

Another frequency limiting factor is the inductance of the lead to each tube element. Because any conductor possesses self-inductance, the internal leads to the tube elements and the elements themselves, as well as the tube pins, have some inductance. For example, within a tube operating above 30 mc, circuit calculations must take into consideration the effective values of inductance. This inductance is in series with the plate, grid, and cathode, and although the actual inductance of a lead is usually small, the reactance offered at frequencies of several hundred megacycles becomes appreciable.

While these inductances do not necessarily impair the efficiency of the oscillator, they may represent a major portion of the inductance of the tuned circuit and limit the frequency by setting a minimum limit on the inductance. Furthermore, since the cathode lead is frequently common to both plate and grid circuits, feedback may take place through it and produce an additional loss of efficiency.

Transit Time

The importance of transit time at UHF and higher frequencies is mentioned in Basic Electronics, NavPers 10087-B. Further details are presented in the following paragraphs.

The effect of transit time is of special concern in connection with the input impedance of the tube. The signal applied to the grid causes a flow of electrons past the control grid, which in turn causes a current to be induced into the grid. This induced grid current may flow either into or out of the grid, depending on the relative grid voltage at the time. Part of the current flowing in the grid is the current which charges the grid to plate capacitance (C_{pg}, fig. 12-7). The voltage which produces this current is the vector sum of the input voltage (grid to cathode) and the output voltage (across the plate load).

Grid current flow absorbs power from the input signal, even though the grid is always negative, and has the same effect as if a shunt resistance and a shunt capacitance were connected across the grid and cathode terminals of the tube. The loss of signal energy brought

977

about in this manner is the most important effect of transit time, and the loss increases as the frequency increases.

At lower frequencies with a resistive load, the input and output voltages are (for practical purposes) 180° out of phase and add algebraically to determine the charging current for the grid to plate capacitor. This current is 90° out of phase with the input voltage. However, at higher frequencies where transit time is an important factor, the plate current lags appreciably behind the input voltage. At these frequencies, the plate voltage is less than 180° out of phase with the input voltage, and the voltage across the capacitor lags the input voltage slightly. As a result, the charging current is no longer 90° out of phase, but now has an in-phase component. The in-phase current results in power being consumed in the grid circuit. The consumption of power is effectively the same as adding a high resistance between the grid and cathode, with the resistance decreasing as the frequency is increased.

REDUCING TRANSIT TIME EFFECTS.— Transit time effects can be minimized by scaling down tube dimensions and increasing operating voltages. Miniaturization is utilized widely. Amplifiers designed for use above 30 mc usually have close interelectrode spacing. Many transmitting tube types are very small in proportion to their power ratings, and require cooling by forced air draft.

Where close spacing is utilized, the distance from the cathode to grid is particularly important. Preventing the electrons from leaking from cathode to plate around the ends of the control grid supports is important, because such leakage would result in increased transit times.

Screen grid tube types have naturally shorter transit times than triodes, and are used in many VHF/UHF/microwave equipments to reduce transit time effects.

Miscellaneous Effects

Other effects on electron tubes at the higher frequencies are caused by grid gas current, grid emission, and heat radiation.

In any electron tube there are always some molecules of gas, because it is impossible to produce a perfect vacuum. When electrons collide with these molecules, positive ions are created and are attracted to the negative control grid. This causes a grid current to flow when the grid is negative. The grid current thus produced is small but has the effect of making the grid less negative, which is undesirable in view of the effects of input resistance in this frequency range.

Any metal emits electrons if heated sufficiently, although some are much more efficient in this respect than others. In miniature tubes suitable for use at frequencies higher than 30 mc, the grid is subjected to heating by the nearness of the cathode as well as by the in-phase grid currents. Some electrons strike the grid even though it is negative, causing the possibility of secondary emission. As a result, there is a possibility of both primary and secondary emission from the grid. This adds to the space charge and is undesirable because it varies erratically. The effect can be reduced by plating the grid with a metal that does not emit electrons easily. Gold is particularly effective and is used where the type of operation is critical enough to warrant the expense. Another method, somewhat less effective, is spraying the grid with finely powdered boron carbide.

The radiation of heat from the plates of air-cooled tubes becomes a factor of importance because the tube efficiency is reduced as the frequency is raised. For a given power input, a reduction of efficiency causes higher plate dissipation. This means that the input power must be reduced to keep the plate dissipation from going above the rated value and causing serious overheating. When the input power is decreased, however, the useful output power drops.

The most common method of improving the thermal radiation of the tube plate consists of coating the plate with finely divided carbon. The resultant dull black surface is about 60 percent more efficient as a heat radiator than polished metal.

Overcoming Tube Limitations

There are several ways to reduce the effect of interelectrode capacitances in vacuum tubes, though none is completely satisfactory. One is to move the electrodes farther apart; however, this is not desirable because it increases the transit time. Another method is to reduce the size of the tube and electrodes; this is satisfactory except for one ill effect. It decreases the power handling ability of the tube, varying directly with the square of the factor by which

978

the electrodes are reduced. Another method is to separate the leads and to bring them out of the envelope at the point nearest the electrode; this results in a slight decrease in the capacitances.

Similarly there are several ways to reduce the inductances of the leads. Bringing out electrode leads through the envelope at the nearest point decreases the inductances of the leads as well as the capacitances. Another method is to make double connections to the electrode. This makes two parallel inductances, thus cutting the lead inductance in half. Another method is to arrange the leads as extensions of the external transmission lines which are the resonant elements of the circuit. Thus the interelectrode capacitances and lead inductances are incorporated as part of the tuned circuit. (See fig. 12-8.)

It is possible to minimize the inefficiency previously mentioned by using a tube that has two separate external cathode connections.

Figure 12-8.—Tuned grid, tuned cathode oscillator.

When one cathode lead is used for the grid return and the other for the plate circuit, the unwanted feedback is prevented since the grid and plate currents do not flow in a common lead inductance.

For reducing transit time, closer spacing of the electrodes may be employed. Closer spacing of electrodes, however, causes higher interelectrode capacitances. Therefore, it can be used only when the electrodes are made smaller.

Transit time may also be reduced by the use of higher plate voltages. For this reason UHF oscillators operate at very high plate voltage. The fact that a radar and other pulsed transmitters do not operate continuously is an advantage in that high enough voltages may be used to reduce transit time without exceeding the maximum power rating of the tube. Operating with high voltages does, however, necessitate some precautionary measures (such as separating the leads to avoid the presence of excessive voltage gradients in or on the surface of the glass envelope, and avoiding sharp projections on the high voltage leads or electrodes to prevent arcing).

LIMITATIONS DUE TO EXTERNAL CIRCUITS

In addition to the limitations placed on the operating frequencies of oscillators by the tubes themselves, additional limitations are imposed by the external circuits. An increase in frequency causes a rather rapid increase in power losses in the external oscillatory (tank) circuit. These losses are due, primarily, to the skin effect of current in conductors, and to radiation from the conductors.

Skin Effect

Skin effect causes a considerable increase in the resistance in an electron tube circuit. This results in a lower Q and increased I^2R losses. To prevent skin effect losses, conductors are made large in size and tubular in shape since current flows only in the surface at and above UHF frequencies. In addition they may be plated with silver, since it has a higher conductivity than copper. At microwave frequencies current flow will be in the silver plating.

MICROCOPY RESOLUTION TEST CHART
NATIONAL BUREAU OF STANDARDS-1963-A

or $\frac{2\pi r^2}{2}$, or πr^2. This is the most commonly used formula for the area of a circle.

An ellipse is shown in figure 2-20. The longer axis AB is called the major axis, the shorter axis CD the minor axis. Call the length of the major axis a and that of the minor axis b. The area equals the product of half the major axis times half the minor axis times π; or $A = \frac{a}{2} \times \frac{b}{2} \times \pi = \frac{\pi ab}{4}$.

Areas of irregular figures which are drawn to scale may be determined by use of an instrument called a planimeter. The planimeter is described in chapter 3.

Solid Figures

Solid figures are three-dimensional; that is, they have length, width, and height. Figure 2-21 shows various common solid figures; refer to the illustration as you study the following definitions and statements concerning solid figures.

Figure 2-21.—Three-dimensional shapes.

The portions of planes which form solid figures are called faces.

Faces which are the top and bottom of the figures (as usually depicted) are called bases.

The sides are called lateral faces or faces.

Lateral edges are formed by the intersection of lateral faces.

A prism is a figure whose bases are similar polygons and whose faces are parallelograms.

A pyramid is a figure whose base is a polygon and whose sides are triangles.

A circular cylinder has circular bases.

A circular cone has a circular base: the lateral surface is formed by a line which moves around the circle from a fixed point.

Prisms and pyramids are square, rectangular, triangular, hexagonal, and so on, according as their bases are squares, rectangles, triangles, hexagons, and so on.

The lateral edges of a right prism or right cylinder are perpendicular to the base; the vertex of a right pyramid or a right cone falls on a line perpendicular to the center of the base; an oblique prism or pyramid or cylinder or cone does not meet these requirements—that is, it slants.

A truncated prism or pyramid or cylinder or cone is the portion of the figure between the base and a plane which cuts the figure oblique to the base.

The frustum of a pyramid or cone is the portion of the figure between the base and a plane which cuts the figure parallel to the base.

A tetrahedron is a figure with four faces.

A cube is a prism whose six faces are square.

A sphere is a solid bounded by a surface all points of which are equally distant from a point inside called the center.

Volumes

The formula for finding the volume of a rectangular solid is $V = \ell wh$, or the volume of a rectangular solid is equal to length times width times height. Since ℓ times w is the area of the base, you may let A_B stand for the area of the base and express the volume another way: $V = A_B h$, or volume is equal to area of the base times height. When you use a formula for the volume of a solid, like $V = \ell wh$, the length, width, and height must be expressed in the

142

same unit of measurement, and the volume, V, will be expressed in terms of the cube of this unit. For example, refer to figure 2-22 which represents a rectangular prism with a base 2 ft by 2 ft and a height of 3 ft; there are 12 cubic feet in the solid.

Figure 2-22.—12 cubic feet in rectangular solid.

In the case of a cube, remember that there is a difference between, for example, 2 cubic feet and a 2-foot cube. Two cubic feet may be represented by two of the little cubes in figure 2-22. But a 2-foot cube is a block which measures 2 ft on each edge and has a volume of 8 cubic feet.

For the volume of any prism, then, you simply determine the base area (rectangle, square, triangle, or whatever) by the appropriate method and then multiply the base area by the height. In the case of an oblique prism, the height is the perpendicular distance between the bases and not the distance along a sloping edge (called the slant height).

From the standpoint of volume calculation, the only difference between a cylinder and a prism lies in the fact that the base of a cylinder is a circle rather than a polygon. Therefore, the volume of a cylinder is again equal to the product of the base area times the height. But you determine the base area from the formula πr^2.

The best way to approach the problem of determining volume of a cone or pyramid is on the basis of the fundamental fact that the volume of a cone equals one-third of the volume of the corresponding cylinder, while the volume

Figure 2-23.

of a pyramid equals one-third of the volume of the corresponding prism. Therefore, for any of these solids, volume equals base area times height divided by 3.

The formulas for the volumes of frustums of pyramids and cones involve the areas of both the upper and lower bases. The formula for the volume of a sphere involves π and the radius of the sphere. These formulas together with the formulas discussed in the preceding paragraphs are summarized in figure 2-23.

TRIGONOMETRY

Trigonometry is that branch of mathematics which deals with the relationships among the sides and angles of triangles and especially with methods of deducing required parts from other given parts.

Trigonometric functions are various ratios whose values vary with the size of angles. The functions of angles can best be illustrated by means of a "circle of unit radius" like the one shown in figure 2-24. A grid coordinate axis is inscribed within the circle. Angles are generated by the motion of a point P counterclockwise along the circumference of the circle. The initial leg of any angle is the positive leg of the x axis, that is, line OC in the illustration. The other leg is the radius r, at the end of which the point P is located; this radius always has a value of 1. Because the positive and negative legs of the axes also have a value of 1,

Figure 2-24.—Circle of unit radius.

Figure 2-25.—Trigonometric functions.

the value of each of the 10 subdivisions shown is 0.1. For any angle the point P has three coordinates: the x coordinate, the y coordinate, and the r coordinate (which always has a value of 1). The functions of any angle are, collectively, various ratios which prevail among these coordinates.

Three of these functions are called the sine, the cosine, and the tangent. The numerical values of these three functions for angles from 0° to 90° are shown in the table of trigometric functions in figure 2-25.

The ratio between y and r (that is, $\frac{y}{r}$) is called the sine of the angle. In figure 2-24 the y value of point P is 0.5; therefore the sine of 30° is $\frac{y}{r} = \frac{0.5}{1} = 0.5$. In the table in figure 2-25 you can

see that the value of the sine of 30° is 0.500. Graphically, the sine is indicated in figure 2-24 by line AP.

The ratio between x and r (that is, $\frac{x}{r}$) is called the cosine of the angle. In figure 2-24 the x value of point P is about 0.87; therefore the cosine of 30° is $\frac{x}{r} = \frac{0.87}{1} = 0.87$ In the table in figure 2-25 you can see that the cosine of 30° is 0.866. Graphically, the cosine is indicated in fiugre 2-24 by line OA.

The ratio between y and x (or $\frac{y}{x}$) is called the tangent of the angle. The tangent of 30°, then, is $\frac{y}{x} = \frac{0.500}{0.866} = 0.578$, which agrees with the value shown in the table in figure 2-25. The tangent is indicated graphically by the line CB, drawn tangent to the circle at C and intersecting the extended r at B. As you can see by the line projected from B to the ordinate, the y value of CB is, by scale, about 0.58.

The three functions illustrated in figure 2-24 are called the "direct" functions. For each direct function there is a corresponding "reciprocal" function--meaning, a function which results when you divide 1 by the direct function. You know that the reciprocal of any fraction is simply the fraction inverted. Therefore, for the direct function "sine", which is $\frac{y}{r}$, the reciprocal function (called the "cosecant") is $\frac{r}{y}$. For the direct function "cosine", which is $\frac{x}{r}$, the reciprocal function (called the "secant") is $\frac{r}{x}$. For the direct function "tangent", which is $\frac{y}{x}$, the reciprocal function (called the "cotangent") is $\frac{x}{y}$.

For a detailed discussion of trigonometry, refer to chapter 6 of Mathematics, Volume 2, NavPers 10071-A.

MECHANICS

Mechanics is the oldest and simplest branch of physics. It deals with the motion of bodies and the equilibrium of forces. Before studying this section of this chapter, you should study chapters 1 through 9 of Basic Machines, NavPers 10624-A. That text covers simple machines—the lever, block and tackle, wheel and axle, inclined plane and wedge, and the screw. The concepts of work, power, force, energy, and pressure are also covered.

Force is an action upon a body which tends to set it in motion or to change its state of motion. Where there is an equilibrium of forces, no change occurs, but each force must be balanced by one or more other forces acting in the opposite direction.

Work is done when a resistance is overcome by a force acting through a measurable distance. Therefore, in mechanics, work is a measurable quantity based on resistance (a measurable quantity), force (a measurable quantity), and distance (a measurable quantity). The measurement of quantities is basic to all physics.

Vectors

All quantities can be classified in one of two groups--scalar quantities or vector quantities. A scalar quantity can be specified by magnitude alone, for example, quantities of money, wheat, books, etc.

There are certain types of quantities which we must deal with in physics and mathematics which cannot be completely specified by magnitude alone, but which involve also the idea of direction. These quantities are called vector

Figure 2-26.—Parallelogram of forces.

Figure 2-27.—Triangle of forces.

quantities. Examples are displacement, velocity, acceleration, and force. They can be represented and analyzed graphically by means of lines of appropriate length and direction, called vectors.

For example, a force can be represented by a straight line. One end of the line represents the point at which the force is applied. The direction of the line, indicated by the arrowhead, represents the direction in which the force is applied. The number of units in the length of the line represents the number of units of force.

Suppose that two forces are acting on a particle from different directions, and you wish to know the total effective force being exerted on the particle. This force which represents the total of two or more forces is called the resultant. You can find this resultant by drawing a diagram representing the two forces acting on the particle as shown in figure 2-26A. Then complete the diagram by drawing dotted lines parallel to the lines of the forces to form a parallelogram. The diagonal of this parallelogram is the resultant of the two forces, as shown in figure 2-26B. That is, force OA and force OB cause the same result on the particle as force OC.

In figure 2-26, the spatial relationship of the forces in relation to their point of application is maintained. The same resultant can be found by constructing a triangle, as shown in figure 2-27. You can start with either of the forces and add the second at its end, being careful to preserve the length and direction, as shown in figure 2-27A. Now, the third side of the triangle is the resultant. Notice, that it is the same length as the diagonal in figure 2-26.

This is the same as adding distances and directions. For example, if a man walks 3 miles east and then turns and walks 4 miles north, and you wish to find the distance in a straight line between the point where he started and the point that he finally reached, you can add the displacements by drawing a triangle as shown in figure 2-28. You can find the length of the third side by measuring it directly, or by mathematics if greater accuracy is desired.

Figure 2-28.—Adding directions of quantities.

In adding vectors graphically, the added quantities are placed tail to head. The sense of the resultant will be from the tail of the first vector toward the head of the last vector.

Figure 2-29.—Finding two components of a force.

Just as it is possible to find the resultant vector when the component vectors are known, it is likewise possible to break down a known resultant into any number of desired components. In figure 2-29A, the resultant and the lines of action of the two components are given. When the parallelogram is completed with lines parallel to the two forces, the component forces are defined, as shown in figure 2-29B.

In figure 2-30, the force of the wind against the sail of a sailboat, represented as the force vector R, has been resolved into components. For simplicity, the sail is considered to be flat in this illustration. In figure 2-30A, R has been resolved into components A and B. A, parallel with the sail, produces little effect, but B acts on the boat through the mast. However, to find the force effect of B on the movement of the boat through the water, it is resolved, in figure 2-33B, into the components C, parallel with the keel of the boat, and D. D produces very little motion because the boat is not built to move sideways in the water. The component C represents the force producing forward movement of the boat by a wind blowing in the direction of the force vector R.

Polygon of Forces

Up to this point, the effect of only two forces acting at a single point has been considered. Suppose that more than two forces are involved.

Figure 2-30.—Resolving a force vector into components.

Figure 2-31.—Using the parallelogram construction to find the resultant of more than two forces.

The resultant of more than two forces can be found by finding first the resultant of two forces and then using it with another component force to find another resultant, etc. For example, in figure 2-31, forces OA and OB yield the resultant OX. Then a parallelogram is constructed using OX and force OC, which yields the resultant OY. Thus, OY is the resultant of OA, OB, and OC.

However, as the number of forces increases, this method becomes increasingly complex. In its place, a polygon of forces is used. For example, take the three forces shown in figure 2-32 and, placing them tail to head, construct an open polygon, as shown in figure 2-32B. The arrow which closes this polygon, as shown in figure 2-32C, is the resultant of the forces in its proper length and direction.

Note that the resultant in figure 2-32 has its arrow pointing in the direction around the poly-

Figure 2-32.—Polygon of forces.

Figure 2-33.—Three forces in equilibrium.

Figure 2-34.—Three nonparallel forces acting on a body to produce equilibrium.

gon opposed to that of the given forces. A force parallel and equal to this arrow acting at O represents the resultant in position, as well as in length and direction, as shown in figure 2-32C.

A problem in vectors can be solved graphically if it contains not more than two unknowns. These unknowns may be:

1. The magnitude and direction of one vector.
2. The magnitude of one vector and the direction of another.
3. The magnitude of two vectors.
4. The direction of two vectors.

Conditions of Equilibrium

Statics is that branch of mechanics which is the study of the equilibrium of forces. It is concerned with bodies at rest and the forces

Figure 2-35.—Polygon of forces in equilibrium.

Figure 2-36.—Parallel forces acting on a body to produce equilibrium.

which keep them at rest. When an unbalanced force acts on a stationary object, the object will move, but that does not mean that there is no force involved when the body is stationary. Instead it means that the forces acting on the body are in balance. A picture hanging on the wall is stationary, but there are a number of forces acting upon it.

Suppose you are dealing with a structure in which the forces are in equilibrium. How would you represent these forces? Suppose that at one point on a stationary body three forces are applied as shown in figure 2-33A, and these forces are in equilibrium. That is, they cause no movement at the point of application of the forces.

You can solve this problem by drawing a triangle of forces, as shown in figure 2-33B. Since the forces are in equilibrium, force F_3 must be equal to forces F_1 and F_2, and the triangle must be a closed triangle. Now look at the side F_3 with side OA in figure 2-27 and with the diagonal OC of the parallelogram in figure 2-26. In other words, the equilibrant, a force which is sufficient to maintain equilibrium between forces, must be equal to the resultant of these forces and opposite in direction.

For example, the weight of a picture, which is equal to the pull of gravity upon it, is balanced by the tension in the cords by which it hangs on a nail in the wall. In other words, the sum of all the force vectors must equal zero, as shown in figure 2-34. When three forces acting on a body are not parallel, as shown in the figure, their lines of action must pass through a common point to produce equilibrium.

If more than three forces are involved, the force polygon may be used. If the forces act at O as shown in figure 2-35A, and they are in equilibrium, the polygon of forces will appear as shown in figure 2-35C. A closed polygon of forces, like a closed triangle of forces, represents forces in equilibrium. Look at figures 2-35 and figure 2-32.

The weight of a body can be considered to be a system of parallel forces acting on the body. When these forces are replaced by a resultant, the point of application can be represented by a single force acting downward at the center of gravity, or centroid. When three or more parallel forces act on a body to produce equilibrium, the resultant of these parallel forces is equal and opposite to the equilibrant, as shown in figure 2-36.

However, the forces acting on a body may be parallel, equal, and opposite, and still fail to produce equilibrium. In this case, the forces are acting at different points on the body. Such forces, producing a rotary motion, are called

Figure 2-37.—A. A couple acts upon a body to produce rotation.
B. Two couples acting upon a body may produce equilibrium.

Figure 2-38.—A. The line of the moment, or torque, of a force is always perpendicular to the line of action of the force.
B. Maximum moment.
C. Minimum moment.

a couple. (See fig. 2-37A.) The tendency to produce rotation is called the moment of the couple, and it is measured by taking the product of one of the forces multiplied by the distance between the two, or the arm of the couple.

In order to maintain equilibrium when a couple is acting upon a body, a second couple, consisting of two other equal and opposite forces, is required. The moments of the two couples must be equal and they must tend to rotate the body in opposite directions. (See fig. 2-37B.)

Conditions for Stability

As has been stated, when forces act at different points on a body instead of at one point, they tend to cause rotation of the body. The tendency toward rotation caused by any force is equal to the force multiplied by its distance from the center of rotation. The center, or axis, of rotation may be a stationary fulcrum as in the case of a lever, prybar, or seasaw, or it may be the center of gravity of the object, as in the case of the roll and pitch of a ship or airplane.

This product of force times distance from the axis is called moment or torque. It must be remembered that the moment arm is not necessarily measured from the point of application of the force but is always measured perpendicularly to the line of action of the force. (See fig. 2-38.)

For a body to remain in a stable condition, the sum of all horizontal forces must equal zero, the sum of all vertical forces must equal zero, and the sum of all moments must equal zero. Thus,

$$\Sigma H = 0,$$
$$\Sigma V = 0,$$
$$\Sigma M = 0,$$

in which the Greek capital sigma (Σ) represents the term SUM OF, H represents the horizontal forces, V represents the vertical forces, and M represents the moments. These three formulas may also be written

$$\Sigma F_x = 0,$$
$$\Sigma F_y = 0,$$
$$\Sigma M_O = 0,$$

in which F_x represents the X forces and F_y the Y forces in a system of rectangular coordinates, and M_O represents the moments.

Radiation

Radiation, the other cause of power loss, is due to incomplete cancellation of electromagnetic fields in the region surrounding the circuit. When the frequency is low enough so that the spacing between two parallel conductors equals only a very small fraction of a half wavelength, there is almost complete cancellation of fields in all directions. At higher frequencies, however, the same spacing would represent a larger fraction of a half wavelength. This means less cancellation. In extreme cases (for example, where the spacing is a half wavelength) the fields add in the direction of the plane containing the two conductors. This causes the tuned circuit to radiate energy like an antenna. Therefore, as the frequency increases, it is necessary to reduce the spacing between the parallel elements. However, there is a limit; too close spacing will result in arcing of the tank circuit. Another means of eliminating radiation is the use of concentric lines instead of open wire line. This eliminates radiation entirely, since the outer conductor acts as a shield which prevents the electromagnetic field from expanding into space.

Limits of Inductance and Capacitance

At UHF frequencies and above, it is necessary that the inductances and capacitances in the oscillatory circuit be very small. The lower limit of capacitance is the sum of the interelectrode capacitances and the distributed capacitance of the leads. The lower limit of inductance is the lead inductance plus the inductance necessary to connect the tube electrodes externally. UHF oscillators approach both these limits; the only capacitance in the tank circuit often is a small trimmer capacitor for fine tuning adjustments, and the inductance often is the shortcircuited transmission line less than one-quarter wavelength long. (See fig. 12-9.)

To obtain smaller values of inductance, the length of the line is decreased. Frequently the tank circuit is located near a flat surface and parallel to it. The flat surface acts as a shield and, while it does not affect the electrical length of the line, it does lower the characteristic resistance of the line.

At microwave frequencies, even the small amounts of inductance and capacitance mentioned above prove to be excessive, so that at microwave frequencies the resonant cavity is almost exclusively used as the oscillatory circuit.

Figure 12-9. —Parallel wire resonant circuit.

LIGHTHOUSE TUBE OSCILLATOR

The lighthouse tube oscillator is a single tube oscillator used in test equipment and low power transmitters. The lighthouse tube, which gets its name from its peculiar construction, will operate at frequencies as high as 4,000 mc. Its plate, grid, and cathode connections are arranged so that it may be mounted directly in the tuning assembly. (See fig. 12-10.) The component called the tuner consists of three coaxial cylindrical conductors, of which the inner cylinder makes contact with the plate, the next with the grid, and the outer conductor with the shell of the tube.

The outer conductor provides an RF connection to the cathode through capacitance. The space between the cathode and grid conductors forms a coaxial cathode line which in turn is shorted by means of a plunger. The insulation at the tube base between the cathode and the cathode shell (or external connection) is the dielectric between the rings which form the cathode capacitive coupling. If this capacitive coupling were not used, the grid would have a d-c path from its cylinder through the plunger and the cathode cylinder to the cathode. This capacitance in the tube base is great enough to form a virtual short circuit for RF. The d-c grid to cathode path consisting of R_g and C_g forms the grid leak bias circuit.

In the plate circuit, the plate line consists of the grid and plate conductors. It is open circuited at the end away from the tube. The plate voltage is applied to the plate lead through the plate tuning rod at the point where the plate line is shorted. This point is one-quarter

CHAPTER 3

DRAFTING INSTRUMENTS AND EQUIPMENT

Few skilled workers can do a good job with poor tools, and draftsmen are no exception. Drafting instruments and equipment should be well made and should be kept in good condition. If a man is a poor draftsman, the best instruments in the world will not make him a good draftsman. On the other hand, a good competent man will do better work if he is furnished good instruments and materials, and since he knows the importance of good equipment, such a competent man will make every effort to keep it in good condition. Each instrument and piece of equipment was designed to do a certain job. Learn what that job is, and use your tools to do the job for which they were designed. A good set of drafting instruments will last a lifetime if given proper care.

Observe these rules:

1. Have a place for each piece of equipment and keep it there when you are not using it.

Figure 3-1.—Drafting table.

Figure 3-2.—Light table.

2. Keep your instruments in their case when they are not in use.
3. Keep your pens clean.

The basic equipment for a simple drafting assignment consists of a drawing board with a straight working edge on at least one side, a T-square, a set of triangles, scales, pencils, ink, a protractor, an eraser, curves for drawing irregular curved lines, and a set of drafting instruments. Your instrument set should include ruling pens, compasses, and dividers. Special instruments will be required for more complicated drawings.

This chapter covers the nomenclature, use, care, and maintenance of the basic equipment, the basic instruments, and some of the special instruments. This chapter does not include coverage of lettering pens and pen points, lettering guides, or mechanical lettering devices. These items are covered in chapter 9, an entire chapter devoted to lettering.

Figure 3-9.—Using T-square and triangle(s) to draw lines at angles of 15, 30, 45, 60 and 75 degrees to the horizontal.

DRAWING TABLES AND BOARDS

Navy drafting rooms are generally equipped with drafting tables such as the one shown in figure 3-1. The top of the table is, in effect, a drawing board. The board can be adjusted to various angles to suit the man using the table. Various other features are pointed out in figure 3-1 by the manufacturer of this particular table.

Drafting tables are available in various sizes and styles and with various arrangements of drawers. One type of drafting table which is of great convenience in the drafting room is the light table or tracing table such as the one shown in figure 3-2. A light table has a glass working surface with fluorescent lights underneath. This arrangement greatly facilitates the tracing of prints, soiled tracings, or other relatively opaque drawings.

When a drafting table is not available, draftsmen use a drawing board which is generally made of white pine, basswood, or of some other soft wood. It should have a smooth top surface and a straight working edge at the side. A typical drawing board is shown in figure 3-3.

Sometimes a drawing board is raised on wedges placed under the board so that, when the board rests on a table, the drawing surface slopes toward the draftsman. A recommended maximum slope is 1 vertical to 8 horizontal.

It is common practice to cover drawing boards, especially the larger and more expensive ones, to ensure cleanliness, to protect them against nicks and scars, and to provide a resilient surface for pencil drawings. A desirable drawing board cover is made of some material that will lie flat with a minimum of puckers. It should have enough body to provide protection; it should not be too hard or too soft; and it should be strong enough to withstand considerable use before being renewed. If it is too hard, the compass needle point will not penetrate it, and the compass will not hold its position. If it is too soft, it will become grooved and scarred quickly. Manila paper is commonly used to cover drawing boards. There are, however, papers on the market with a high gloss waterproof finish on one side which will withstand many cleanings. Also, some grades of linoleum have been found satisfactory; the sheet of linoleum may be applied to the board with linoleum paste.

More light is required for drafting than for normal administrative office work. If overhead lighting is insufficient, lamps should be obtained. The most popular drafting lamp is the floating-arm type of fluorescent fixture which clamps onto the desk or drafting table.

T-SQUARES AND STRAIGHTEDGES

The T-square gets its name from its shape. It consists of a long, straight strip, called the blade, which is mounted at right angles on a short strip, called the head. The head is mounted under the blade so that it will fit against the edge of the drawing board while the blade rests on the surface as shown in figure 3-3. T-squares vary from 15 inches to 72 inches in length, with the 36-inch length the most common.

The T-square is used for drawing horizontal lines (see fig.3-4), and it serves as a base for the triangle when vertical and inclined lines are drawn. Always draw lines along the upper edge of the blade. Move the T-Square up or down to position by sliding the head along the edge of the drawing board with your left hand.

Handle your T-square carefully. If dropped, it may be knocked out of true and become useless. The T-square blade should not be used as a guide for the knife in cutting paper.

Before beginning a new job, you should test the top edge of your T-square for warp or nicks. Draw a sharp line along the top of the blade. Turn the T-square over and redraw the line with the same edge. If the blade is warped, the lines will not coincide.

If the blade swings when the head is held firmly against the edge of the drawing board, the blade may be loose where it is joined to the head, or the edge of the T-square head or of the drawing board may be warped. You can usually tighten a loose blade by adjusting the screws which connect it to the head, but if it is out of square or in bad condition you should select a new T-square.

To keep a good T-square true, hang it up or lay it on a flat surface when you are not using it. Hang the T-square up by the hole in the end of the blade, and not by the head.

For large drawings, many draftsmen prefer a parallel straightedge to a T-square. As shown in figure 3-5, the parallel straightedge is permanently attached to the drawing board by a system of cords and pulleys so arranged as to give exact parallel motion to the straightedge as it is moved over the board.

The parallel straightedge has two fundamental advantages over the T-square: supported at both ends, it maintains parallel motion automatically; it may be moved up or down the board with pressure at any point along its length. These advantages become particularly significant when you are working on large drawings, because a T-square tends to become unwieldy and inaccurate when you work near the blade end of a long T-square.

Steel straightedges (fig. 3-6) are used for drawing long straight lines. Sometimes a long T-square blade is used as a straightedge, but the steel straightedge is superior because its heavier weight helps you keep the straightedge exactly in position. Putting tape at both ends of the straightedge greatly reduces unwanted movement. Using the beveled edge for inking reduces the chance of ink running under the straightedge.

TRIANGLES

Right-angle triangles are used in combination with the T-square or straightedge to draw vertical and inclined lines. Plastic triangles are preferable to wooden ones because they are transparent and you can see the work underneath. The most common triangles are the 45° and the 30°-60°, shown in figure 3-7. You will note that both have one 90° angle, or right angle, and that one has two 45° angles while the other has one 60° and one 30° angle. Another triangle sometimes used is the 22 1/2°-67 1/2° triangle.

Vertical lines are drawn by using the T-square as a base for one of the triangles. With the T-square in position, place one edge of the triangle against the blade and draw the vertical line along the vertical edge, as shown in figure 3-8. (Left-handed draftsmen reverse the triangle.)

You can use the same method to draw lines at an angle of 30, 45, and 60° to the horizontal T-square. When you reverse the triangle, you can draw the same angle in the opposite direction. (See fig. 3-9A.)

These angles may be referred to the vertical as well as to the horizontal, because the difference between the horizontal and vertical is 90°. You merely subtract the degrees of a horizontal angle from 90° to find the degree of the vertical angle corresponding to it. For example, an angle 30° from the horizontal will automatically be 60° from the vertical.

Now suppose you want to draw a line that forms an angle of 75° with the horizontal or 15° with the vertical. You can do this by using both the 45° triangle and the 30-60° triangle with the T-square. Rest the side of the 30-60° triangle against the T-square and set the 45° triangle above it, as shown in figure 3-9B. The 30° angle and the 45° angle add up to 75°. You can get the opposite result, or 15° to the horizontal, by readjusting the triangles.

Parallel vertical or inclined lines are drawn by sliding the triangle along the blade of the T-square. (See fig. 3-10.) You can draw a line parallel to any given line by placing the side of the triangle flush with the line, and fitting the T-square or straightedge along the base. Then slide the triangle to any desired point and draw a line.

A line perpendicular to another line can be drawn by using the adjacent sides of the 90° angle. If one side is parallel with a line, the adjacent side will be perpendicular to it. Place the long side of the triangle against the straightedge. Draw a line along one side. Then slide the triangle along the straightedge until the adjacent side is perpendicular to the drawn line. (See fig. 3-10.)

The techniques in the preceding paragraphs are the same if a straightedge other than a T-square is used. Other straightedges could include a parallel straightedge, a steel straightedge, or the side of a large triangle.

Like other drafting equipment, triangles must be kept in good condition. To prevent warping, you should always lay them flat or hang them up

Figure 3-10.—Drawing parallel perpendicular lines.

Figure 3-11.—Types of protractors.

when they are not in use. Since there is seldom enough drawer space available to permit laying triangles flat without their being thrown around with drawings and other triangles, it is best to develop the habit of hanging triangles up.

If plastic triangles are dropped, their tips may be damaged. Also, triangles may warp so that they do not lie flat on the drawing surface, or the edge may deviate from true straightness. If the tips are bent, use a sharp knife to cut off the damaged part. If the triangle warps out of flat, you may be able to bend it back by hand. If this does not straighten it, leave the triangle lying on a flat surface with weights on it, or hold the triangle to the opposite curvature with weights. If the triangle warps so that the drawing edges are curved or the angles are no longer true, throw it away and get another.

PROTRACTORS

Protractors are used for measuring and laying off angles. They may be circular or semicircular as shown in figure 3-11. The protractors commonly used in drafting rooms are graduated in degrees and divided to 1/2°. With care, angles can be protracted to about 1/4°. The numbering arrangement varies. Semicircular protractors are generally labeled from 0 to 180° in both directions. Circular protractors may be labeled from 0 to 360° both clockwise and counterclockwise or they may be labeled from 0 to 90° in four quadrants.

To measure an existing angle, place the center mark of the protractor at the point of the angle, with the 0° line along one leg. Then note the degree mark which falls on the line of the other leg. To locate the second leg of an angle you are to draw, position the protractor in the same way and use a needle point or a sharp pencil to mark the desired angular value.

Using only the three points on the protractor as described above may result in considerable inaccuracy, particularly if the lines of an angle are to be extended for some distance beyond the protractor. A refinement of the procedure is indicated in figure 3-12. Suppose angle BOA is to be measured. Extend line AO on to C; extend line BO on to D. When you set the center of the protractor at O, make sure that both points c and a are on line AC. Take your reading at point d as well as at point b when you measure the angle. If you are laying off the angle BOA, protract and mark point d as well as point b; this gives you three points (d,0, and b) for establishing line DB. If you are using a semicircular protractor you can't, of course, locate point d; but your accuracy will be improved by lining up c, 0, and a before you measure or lay off the single angle BOA.

Figure 3-14.—Using a french curve to draw a curved line through plotted points.

Figure 3-15.—Spline.

Figure 3-16.—Flexible curve rule.

Figure 3-17.—Ship curves.

CURVES

When you must draw smooth curved lines which are not arcs of circles, you cannot use a compass. For drawing these lines special guides—French curves, splines, and ship curves—are available. Other guides, such as radius curves, may be used instead of a compass when drawing arcs of circles.

French curves come in a variety of shapes and sizes and are made of transparent plastic. (See fig. 3-13.) They are used to draw non-circular curves, such as ellipses, spirals, and parabolas. These curves are usually plotted carefully on a drawing and then the lines are drawn through the plotted points.

When drawing a curve through plotted points:

1. Sketch a light freehand line smoothly through the points.
2. Select a section of a French curve that matches at least three points. Always make sure that the curvature indicated by the plotted points and the curvature of the French curve increase in the same direction. (See fig. 3-14.)
3. Draw the curve between the first points but not to the last point. If you stop short of the last point that matches the French curve, your lines will blend smoothly.
4. Move the French curve to the next position and extend the drawing of the curve, again stopping short of the last point.
5. Continue using this method until you have completed the line.

Splines (fig. 3-15) are used to make long, smooth, irregular curves. They are made of flexible strips of wood, plastic, or metal that can be bent to fit almost any long curve or bend. Metal weights, called ducks are used to hold this spline in place while the line is being drawn.

Flexible curve rules (fig. 3-16) are made of rubber and metal and have a clear plastic ruling edge. They can be bent to a radius of 3 inches and may be adjusted to fit more than three plotted points of a curve.

Ship curves (fig. 3-17) are used primarily for drawing curves peculiar to ship construction. They are made of plastic or wood and come in sets. One curve is usually sufficient to draw the entire curved line, but sometimes several of them must be fitted together to complete the curve.

Another set of irregular curves is called mechanical engineers curves. These curves are similar to some of the French curves and some of the ship curves.

Radius curves may be used instead of compasses to draw arcs of circles. A radius curve is a flat, narrow sheet of plastic curved to conform to the arc of a specific circle. Stamped on each curve is the size of the radius of the circle to which its arc corresponds or some other method of indicating the degree of curvature. These curves are called railroad curves, highway curves, or simply radius curves, all depending on the intended use which is reflected in the method of identifying the curvature. These curves are available in dozens of sizes ranging from 1 1/2-inch radius to 1000-inch radius. Some radius curves are curved throughout as shown in figure 3-18; others have a length of tangent as shown in figure 3-19.

Arcs of long-radius circles may also be drawn with the aid of various adjustable-radius

Figure 3-18.—Radius curve without tangent.

Figure 3-19.—Radius curve with tangent.

Figure 3-20.—Tear drop radius curve.

curve devices currently on the market. These instruments are made of metal and plastic and have clear plastic ruling edges. Some of these devices have coil springs to achieve the proper tension; others make use of the flexibility of

Figure 3-21.—Curves for ellipses, hyperbolas, and parabolas.

Figure 3-22.—Logarithmic spiral curve.

plastic to permit adjustment to the indicated radius.

Other types of regular curves include tear drop radius curves (fig. 3-20), conic section curves (fig. 3-21), and logarithmic spiral curves (fig. 3-22).

TEMPLATES

You can save a great deal of time on jobs on which the same shape or symbol is to appear a number of times by using templates. Most of the templates on the market are made of transparent plastic and offer a wide variety of shapes, including ellipses, hyperbolas, circles, hexagons, and arcs. There are special templates for symbols and shapes used in architectural, civil, electrical, mechanical, and industrial processes drawings. Typical templates are shown in figures 3-23, 3-24, and 3-25.

There are templates for various MIL-STD (military standard) symbols; for example: electrical and electronic symbols, dimensioning and tolerancing symbols, fluid connections symbols, and so on. If the shape you need is not available, it may be worth your while to take time to make your own template from cardboard, plastic, lead, or some other sheet metal.

SCALES

The importance of scales to the draftsman and the mathematical significance of scales were stressed in chapter 2. Once the ratio between the size of the object being drawn and the size of the object as depicted on the drawing has been determined, you will use drafting measuring scales to measure distances on the drawing. Since almost every line on the drawing must be of measured length, measuring scales are in constant use in the drafting room.

Figure 3-26.—Shapes of scales.

Scales vary in scale graduation, style of division, shape, and materials of construction. The most inexpensive scale is made of yellow hardwood—this type of scale is generally used by students in mechanical drawing classes. The scales usually used in drafting rooms are made of plastic or high grade boxwood. The plastic scales, while less expensive than boxwood scales, have clear, accurate graduations. The boxwood scales have white plastic scale faces which are permanently cemented to the boxwood. The boxwood scales are engine divided—that is, the graduation lines are cut by a highly accurate machine.

Various shapes of scales are shown in figure 3-26. The triangular scale provides six scale faces on one rule. The two-bevel scale provides a wide base; the scale faces are always visible. The opposite-bevel scale is easily lifted from the drawing board by tilting it. The four-bevel scale provides four scales on one small rule—this shape is usually used for pocket rules which are 6 inches long. The other shapes of scales are used for rules 12 inches long—the size generally used in drafting rooms.

As to style of division, scales may be open divided such as the 3/16 and 3/32 scales on the architects' scale in figure 3-29. Open divided means that only the main divisions are marked throughout the length of the rule; the extra unit on the end is fully subdivided. Scales may be fully divided such as the engineers' scale shown in figure 3-31. All of the units are fully subdivided throughout the length of the scale. Scales may be double numbered such as the mechanical engineers' scales shown in figure 3-28. This arrangement makes it convenient to measure from right to left as well as from left to right.

The types of scale graduations most often used in drafting rooms in the Navy are the architects' scale, the mechanical engineers' scale, and the civil engineers' scale. The mechanical engineers' scale is often called the mechanical draftsmen's scale to distinguish it from the civil engineers' scale which is fre-

Figure 3-27.—Metric scale.

Figure 12-10.—Lighthouse tube oscillator.

wavelength from the end. This quarter-wave section (which is shorted at the point where B-plus is applied) presents a high impedance to RF from the open ended plate line, and therefore prevents RF from flowing into the power supply.

EQUIVALENT CIRCUITS

The equivalent circuits in figure 12-11 show the evolution of the lighthouse tube oscillator. In (A), the components L_k and L_p represent the inductances of the shorted cathode line and the open circuited plate line respectively. This is a true representation of the actual circuit provided that the cathode line is less than three-quarters of a wavelength long and provided that the plate line is less than a full wavelength long. (The three-quarter wavelength and full wavelength were chosen for this circuit rather than the one-quarter and one-half wavelength due to the fact that at the frequency of operation the latter fractions of a wavelength are inconveniently short.) However, keep in mind that if the cathode line is slightly less than one-quarter wavelength, it acts like an inductance; and if the plate line is slightly less than one-half wavelength, it acts like an inductance. There is no lead inductance shown in the circuit since the lines connect directly to the electrodes. The interelectrode capacitances complete the equivalent circuit.

In (B), the parallel combination of L_p and C_{gp} are represented by X2 and the parallel combination of L_k and C_{gk} by X1. Obviously the reactances X2 and X1 along with C_{pk}, which can be considered as unknown reactances, must form a resonant circuit. The reactance X1 forms a voltage divider circuit along with C_{pk}. Since the voltage across X1 is the voltage fed back to the grid, it must be 180° out of phase with the plate voltage (which can happen only if X1 is a capacitive reactance). This condition leads to the third equivalent circuit, (C), in which the reactance X1 is represented by a capacitor.

An oscillatory circuit requires at least one inductance; therefore X2 must be an inductive reactance. Hence, in (C), the reactance X2 is shown as the inductance L. This circuit is representative of the oscillator circuit only at the resonant frequency. On examining this circuit, notice that basically it is that of a Colpitts oscillator. If X1 is capacitive, C_{gk} must conduct more heavily that L_k; therefore the oscillator frequency must be above the resonant frequency of L_k and C_{gk}. Likewise, for X2 to be inductive the oscillator frequency must be below the resonant frequency of L_p and C_{gp}. Thus the oscillator frequency is between the resonant frequencies of the plate circuit and the cathode circuit.

FEEDBACK

In this oscillator, the amount of feedback depends upon the size of C (fig. 12-11(C)) in relation to C_{pk}. This is a function of the

981

quently called simply the engineers' scale. The latter is also sometimes called the chain scale. But these three scales, while the most common, are by no means the only types of scale graduations available. There are scales graduated in terms of miles to the inch and rods to the inch. There are metric scales such as the one shown in figure 3-27. This rule is divided into centimeters (about 3/8 inch) reading to millimeters on one scale face and centimeters reading to half-millimeters on the other face.

Mechanical Engineers' Scales

Mechanical engineers' scales are used in drawing machine parts and other objects which do not need to be greatly reduced. On these scales, each unit, a fraction of an inch in length, represents a full inch on the object to be drawn. These units are numbered 1, 2, 3, 4, 5, etc., beginning with 0. (See fig. 3-28.)

Figure 3-28.—Mechanical engineers' scales.

The different scales are labeled to indicate the ratio. Sometimes they are marked half size, quarter size, etc., and sometimes they are marked 6 inches = 1 foot, 3 inches = 1 foot, etc., which mean the same thing. On the half-size scale, 1/2 inch is the unit representing 1 inch; on the quarter scale, 1/4 inch is the unit representing 1 inch; on the eighth scale, 1/8 inch is the unit; on the sixteenth, 1/16 inch is the unit. When you have determined the proper reduction for a drawing, select the scale marked with that reduction and, from then on think in terms of big inches on the object and small inches on the drawing.

Usually, mechanical engineers' scales are full divided, with the subdivisions between units indicated by graduations on the entire length of the scale. The subdivisions represent the fractions of an inch as they appear on the regular full-sized scale of a ruler. In other words, the units are divided into halves, fourths, eighths, sixteenths, just as inches are divided on a ruler. Sometimes the subdivisions are carried to thirty-seconds or sixty-fourths.

Architects' Scales

Architects' scales are used for many types or drawings besides architectural drawings. They are designed as reducing scales for measurements in feet and inches. Like engineers' scales they are divided into units by graduations. These units, beginning with 0, are numbered 1, 2, 3, 4, 5, 6, 7, etc. Each unit represents a foot and may be subdivided by graduations into 12 divisions which represent inches.

For example, on the architects' scale which is labeled 3, each unit is 3 inches long, and when this scale is used each 3-inch unit represents 1 foot on the object you are drawing. A 3-inch unit on this scale is graduated into 12 divisions, each of which represents an inch. On other scales, the unit may be 3/32, 3/16, 1/8, 1/4, 3/8, 1/2, 3/4, 1 inch, or 1 1/2 inches. On any of the architects' scales, a unit on the scale represents 1 linear foot on the object. Once you have selected a scale to use in making a drawing, you can think in terms of full feet and inches on the object and small feet and inches on the scale. (See fig. 3-29.)

In figure 3-29, the scale on the upper edge is the common scale measurement that appears on rulers with full inches and feet. It is called the 16 scale because each inch is divided into sixteenths. One of the scales on the lower edge in figure 3-29 is labeled 3/16, which means that 3/16 of an inch on this scale represents 1 foot.

Figure 3-29.—Architects' scale.

Architects' scales are usually open divided. That is, the scale is divided into the units for a foot, and an extra unit preceding the 0 on the scale is subdivided for use in drawing inches to that scale

Figure 3-30 shows the first few units of the 3/4 architects' scale. Let's see how it is used. Remember, on this scale, a unit of 3/4 inch represents 1 foot. Suppose you wanted to measure a distance of 3 feet 10 1/2 inches on this scale. You would first count off the 3 feet on the major graduations. Next count off the 10 1/2 inches on the small graduations which represent inches and fractions of inches and precede the 0 on the scale. This illustrates how all open divided scales are used.

Figure 3-30.—Measuring distance with the architects' scale.

Look again at figure 3-30. You will notice other numbered graduations between the graduations of the 3/4 scale. This is a reverse scale. Since each of these numbers represents two units, this second scale with units half as large as those on the 3/4 scale is a 3/8 architects' scale with 3/8 of an inch representing 1 foot.

When you are drawing an object and are asked to use full scale, half scale, quarter scale, or eighth scale, you will have to think twice before selecting one of the architects' scales. Suppose you want to make a half-scale drawing using the architects' scale. You will have to use the full-size or 16 scale and divide each measurement by 2. Don't use the 1/2 scale, which is intended for drawing each foot on the object as 1/2 inch. To make a quarter-scale drawing with an architects' scale, use the 3 scale, since 3 inches is 1/4 of 1 foot.

Civil Engineers' or Chain Scales

Civil engineers' or chain scales are used in making survey maps and charts and in making machine drawings when the dimensions are given in decimal fractions of inches or feet, rather than in common fractions. The chain scale takes its name from the steel tape which a civil engineer uses. In the past, civil engineers used a real chain, instead of the steel tape they now use, and the name was carried over

An inch on the chain scale is divided by 10, 20, 30, 40, 50, or 60 graduations. The scale is labeled with a large number which indicates the graduations to the inch. Look at the lower scale shown on the instrument in figure 3-31. The large 50 at the end indicates that there are 50 graduations to the inch on that scale. But the graduations themselves are grouped in tens.

The loop attached to the top of the scale in figure 3-31 is made of metal and is called a triangular scale clip. This clip covers the scale faces which are not in use so that your attention is quickly drawn to the scale face in use when the scale is on the drawing board.

Since the civil engineers' scale is decimally divided, it is a very convenient scale to use when plotting charts or graphs. You can select a scale of convenient ratio to fit your paper and let 10 on the scale face be 1 or 10 or 1000 or a billion or whatever tens group you need for the graph.

When you use the chain scale in drawing a map, an inch on the scale represents a specific number of feet on the map. For example, the chain scale labeled 20 has 20 graduations to an inch. When you use this scale, an inch on your

Figure 3-31.—Engineers' scale.

drawing may represent 20 feet. Then one graduation will represent 1 foot. But, an inch on your drawing may also represent 200 feet on this scale, and one graduation will then represent 10 feet. Similarly an inch on the 20 scale may represent 2,000 feet or 20,000 feet or even 200,000 feet.

Taking Measurements From the Scales

To measure accurately with a triangular scale, lay it on your drawing parallel to the line on which the measurement is to be made. The farther edge of the scale should be on the line. Now look down over the scale at this farther edge. Notice that the graduations on the scales are really groves in the surface that are only partially filled with ink. Slide a needle point, or a very sharp pencil, carefully down the groove of the graduation until it touches the drawing paper. (See fig. 3-32.)

Figure 3-32.—Taking a measurement. with a triangular scale.

When you use a needle point, remember that a deep prick mark that breaks the paper is less accurate than a light dent made with the very tip of the needle point. When you use a pencil be sure that it is very sharp. Twirl it in the groove in the scale before removing it, in order to reinforce the pencil dot on the paper.

If a series of distances are to be set off, move the scale only when you have reached the end of it and have more distances to mark. Don't move it for each measurement or you may get a cumulative error which will spoil the drawing.

Note that your pencil touches the scale only for the purpose of marking a point on the paper. Never use a scale as a straightedge for drawing lines. A typical office ruler has a metal edge—it is a scale and straightedge combined. But a draftsman's measuring scale is for measuring only—it is not a ruler. A scale properly used will last for decades, but a scale used as a straightedge will soon have the graduations worn away.

Indicating Scale on a Drawing

There are many ways of indicating the scale on a drawing. Among these are the fractional method, the equation method, and the graphic method.

Figure 3-33.—Graphic scales.

In the fractional method, the scale is indicated as a fraction or a ratio. A full-size scale is indicated as 1/1; enlarged scale as 10/1, 4/1, or 2/1; and reduced scale as 1/2, 1/4, 1/10, etc. Notice that the drawing unit is always given as the numerator of the fraction and the object unit as the denominator. On maps, the reduced scale fraction may be very large (for example, 1/50,000) as compared with the typical scales on machine drawings. On maps, the scale is frequently expressed as a ratio such as 1:50,000.

In the equation method, a certain number of inches on the drawing is set equal to a certain length on the object. Symbols are used for feet (') and inches ("). On architectural drawings a certain number of inches on the drawing is set equal to one foot on the object. A full-size scale is entered as 12' = 1' -0"; and enlarged scale, as 24" = 1' -0"; and a reduced scale, as 1/8"= 1' -0". On civil engineering drawings, one inch on the drawing is set equal to a certain measurement on the object: 1" = 5', 1" = 100', 1" = 1 mile.

In the graphic method, an actual measuring scale is shown on the drawing. Typical graphic scales are shown in figure 3-33.

DRAFTING MACHINES

The drafting machine (fig. 3-34) combines the functions of a parallel ruler, protractor, and scale. Any drafting operation requiring straight parallel lines may be performed advantageously with a drafting machine.

Figure 3-34.—Drafting machine.

Figure 3-35.—Drafting machine with rigid arms.

The majority of drafting machines are constructed so that a protractor head may be moved over the surface of a drafting table without change in orientation by means of a parallel motion linkage consisting of two sets of double bars. The type illustrated in figure 3-35 has rigid metal connecting links or arms, called pin-joint linkage. On the better quality machines of this type, the bearings will have a means of taking up wear.

However, the type of drafting machine shown in figure 3-36, in which the linkage is provided by two steel bands working against one another, is superior to that with pin-joint linkage, because there is less lost motion. The machine in figure 3-36 has steel bands enclosed in tubes, although this type may also have the bands without the tubes. If these bands become loose through wear or expansion, the tension may be increased on them, although this is seldom necessary.

Figure 3-36.—Drafting machine with enclosed steel bands.

The protractor head is a complete circle, graduated in degrees, to which a straightedge or scale may be clamped at any desired angle. If desired, two scales may be attached to the head at right angles to each other. The method of attaching these scales has been fairly well standardized so that a wide variety of scales can be attached or removed as desired. Tapered, dovetailed fittings, with the female part on the control head and the male part on the rule, connect the scales to the drafting machine. (See fig. 3-37.) To remove a scale, a key is used which fits over the head of the adjusting screw. The key, by cam action, pushes the dovetailed fittings far enough apart so that the scale can be removed by hand. To insert a scale, carefully slide the dovetails into place and tighten them by tapping lightly with the palm of your hand.

Figure 3-38.—Roller-type drafting machine.

Figure 3-37.—Fittings for attaching the scale to the drafting machine.

One of the screws holding the fittings to the scale passes through an elongated slot, which allows for some angular adjustment of the scale. This adjustment is for truing the two scales with each other. To adjust them, draw a line by the horizontal scale. Swing the scales 90° clockwise. The scale that had been vertical should now be horizontal and should fit exactly by the line just drawn. If it does not, loosen its adjustment screw, set it right, and then tighten the screw. You will then have the two scales set at a 90° angle to each other.

Correct alignment of the scales with the board is usually accomplished by some adjustment in the control head or linkage of the machine. Any major repairs or adjustments on a drafting machine should be done by an instrument repair man and not attempted in the drafting room.

Figure 3-38 shows a type of drafting machine in which the scales are moved horizontally or vertically by means of rollers or tracks. This type of machine has special advantages when it is used on extra large drawing boards. Angular adjustments can be made to within 1 minute on some of these machines.

COMPASSES

The compass is used for drawing circles or circular arcs. The large compass usually found in a set of drawing instruments is about 6 inches long. The legs are hinged at the top so that they can be set in any desired position. The leg that has the pencil or pen attached usually has a hinged joint in the middle of the leg. The other leg containing the needle point sometimes has a similar hinged joint. (See fig. 3-39.)

Figure 3-39.—Pivot joint compass.

Figure 3-40.—Drawing a circle of given diameter in pencil.

The pencil and pen are interchangeable so that the same compass can be used for either pencil or ink drawings. When the compass is prepared for use, the needle point should be adjusted so that it projects about one sixty-fourth of an inch beyond the pencil lead or ink point. A compass can be obtained with a shoulder on the needle point which prevents the point from sinking too deeply into the drawing surface.

The 6-inch compass is satisfactory for drawing circles to about 12 inches in diameter. For larger circles, an extension bar is provided which may be inserted in the compass between the main body and the pencil or pen leg.

Drawing Circles

To draw a circle with the compass, press the needle point into the drawing paper and move the marking leg around it. After a little practice you will find that you can do this easily with one hand. (See fig. 3-40e.)

When you wish to set the compass to draw a circle of a given diameter, use a piece of scratch paper and follow the steps shown in figure 3-40.

1. Draw a horizontal line with a straightedge.
2. With the straightedge as a base, use a triangle and draw a vertical line intersecting the horizontal line. (See fig. 3-40a.)
3. Measure the radius of the circle with a scale, as shown in figure 3-40b, and draw a second vertical line from this point.
4. Set the needle point at the intersection of the first vertical line and the horizontal line. (See fig. 3-40c.) This is the center of the circle.
5. Set the marking leg to fall on the intersection of the second vertical line and the horizontal line. (See fig. 3-40d.)
6. Draw a half circle with the compass. (See fig. 3-40e.)
7. Now check your work by measuring with the scale the diameter established by this half circle. (See fig. 3-40f.)

Once the compass has been set to the exact radius of the circle, handle it very carefully so as not to disturb the setting. Move the adjusted compass to the drawing where you are going to make the circle. Set the needle point where the center of the circle is to fall and carefully rotate the compass to draw a line describing the circumference of the circle. Do not apply too much pressure on the needle point or it will bore a hole in the paper and you will lose the accurate center mark. Do not hold the legs of the compass while drawing the circle or the pressure of your fingers may change the adjustment.

When using the pencil leg to draw circles smaller than 1 inch in radius, you may keep the pencil and needle legs straight. For larger circles, both legs should be bent so that they are perpendicular to the paper. When using the pen leg, you must bend it at the hinge joint and keep it perpendicular to the paper for all circles, regardless of their size. (See fig. 3-41a.) To draw large circles, insert the extension bar in the pen or pencil leg, as shown in figure 3-41b.

Figure 3-41.—(A) Compass with legs perpendicular to drawing. (B) Compass with extension bar attached.

Beam Compass

For drawing large circles beyond the range of the standard compass, use a beam compass. A beam compass set consists of one or more bars 18 to 70 inches long, a steel needle point, and a pen and pencil point. The bars may be of hardwood or metal. (See fig. 3-42.)

When the beam compass is assembled both the needle point and the marking point can be set at any position along the bar. After setting these points in approximately the correct position on the beam, you can make a final adjustment by means of a small screw on one of the points.

Figure 3-42.—Beam compass.

Figure 3-43.—Stepping off a series of equal distances on a line with the dividers.

Figure 3-44.—Dividing a line into three equal parts.

DIVIDERS

Dividers are similar to compasses, except that both legs are provided with needle points. They are used for transferring measurements and for dividing lines into a number of equal parts.

To lay off distances on a drawing, set the dividers to the correct distance, then transfer the measurements to the drawing by pricking the drawing surface very lightly with the points of the dividers.

To measure off a series of equal distances on a line, set the dividers to the given distance. Then step off this distance as many times as desired by swinging the dividers from one leg to the other along the line. (See fig. 3-43.)

Dividing a given line into equal parts is slightly more complex. For example, figure 3-44 shows how a line is divided into three equal parts. First, set the dividers to a distance approximately one-third the length of the line. Then step off this spread three times. If the three stepped-off distances do not equal the length of the line, increase or decrease the setting of the dividers by one-third the error. Continue this trial-and-error method until the three steps equal the line.

Proportional Dividers

Proportional dividres are convenient for transferring measurements from one scale to another when drawings are to be made to a larger or smaller scale. (See fig. 3-45.) They can also be used to divide lines or circles into equal parts or to get some special ratio such as $1:\sqrt{2}$ or feet to meters.

They consist of two legs of equal length, pointed at each end and held together by a movable pivot. By varying the position of the pivot, the lengths of the legs on opposite sides of the pivot may be adjusted so that the ratio between them is equal to the ratio between two scales. Therefore, a distance spanned by the points of one set of legs has the same relation to the distance spanned by the points of the other set as one scale has to the other.

Figure 3-45.—Proportional dividers.

A thumb nut moves the pivot in a rack-and-gear arrangement. When the desired setting is reached, a thumb-nut clamp on the opposite side of the instrument locks the pivot in place. A scale and vernier are provided on one leg to facilitate accurate setting. The dividers may be set by reference to the table of settings which is furnished with each pair; they will accommodate varying ranges of scales up to 1 to 11.5. However, it is better not to depend entirely on the table of settings. You can check the adjustment by drawing lines representing the desired proportionate lengths and then applying the points of the instrument to them in turn until by trial and error the correct adjustment is reached.

To divide a line into equal parts, set the dividers to a ratio of 1 to the number of parts desired. For instance, to divide a line into 3 parts, set at 3 on the scale. To use the dividers to transfer measurements from feet to meters, draw a line 1 unit long and another line 3.28 units long and set the dividers accordingly. To get the ratio of 1: $\sqrt{2}$, draw an isoceles right triangle and set the dividers to a ratio of the length of the hypotenuse to the length of either of the equal legs. Some proportional dividers have an extra scale for use in getting circular proportions.

The points of the dividers are of hardened steel, and if they are handled carefully these points will retain their sharpness during long use. If they are damaged, they may be sharpened and adjusted without affecting the accuracy of the instrument, but the table of settings will no longer be exact.

Figure 3-46.—Spacing dividers.

Spacing Dividers

Spacing dividers are constructed with multiple legs arranged so that they subdivide the total distance spanned into a number of equal parts. (See fig. 3-46.) The size most frequently used is about 6 inches long and contains 11 points numbered consecutively from 0 to 10. With these dividers, distances up to 9 inches in length may be divided into 10 equal intervals.

Spacing dividers should not be handled roughly, and particular care must be taken to ensure that the points are not injured or bent. If the pivot becomes too loose or too tight, the instrument should not be used.

MAINTAINING COMPASSES AND DIVIDERS

Figure 3-47 shows the three common shapes in which compasses and dividers are made. They may be purchased in either the round, the flat, or the bevel shapes. When you select compasses and dividers, test them for alignment by

Figure 3-47.—Shapes of compasses and dividers. A. Round. B. Flat. C. Bevel.

Figure 3-48.—Testing pivot joint compass for alignment.

Figure 3-50.—Sections of pivot joints.

bending the joints and bringing the points together as shown in figure 3-48.

Older compasses and some cheap modern ones have a tongue joint. (See fig. 3-49.) Because there is no way to tighten this type of joint after it becomes worn, modern pivot joints are more satisfactory. Figure 3-50 shows types of pivot joints found on compasses and dividers.

Dividers should be adjusted so that they may be set without undue friction. They should not be so rigid that their manipulation is difficult, nor so loose that they will not retain their setting. Hairspring dividers are set for the correct friction by skilled instrument makers, and it is inadvisable to attempt adjustments in the drafting room, since a special wrench is needed which is ordinarily not available.

Figure 3-49.—The tongue joint.

Divider points should be straight and free from burrs. When the dividers are not in use, the points may be protected by sticking them into a small piece of soft rubber eraser or cork. When points have become dull or uneven in length, make them even by holding the dividers vertically, placing the legs together, and grinding them lightly back and forth against an oilstone. (See fig. 3-51A.) Then hold the dividers horizontally and sharpen each point by whetting the outside of it back and forth on the stone, while rolling it from side to side with your fingers. (See fig. 3-51B.) The inside of the leg should remain flat and should not be ground on the stone. Neither should any part of the outside of the point be ground so that a flat surface results. In shaping the point, be careful to avoid shortening the leg.

Needles on bow instruments and compasses should be kept sharpened to a fine taper. When they are pushed into the drawing, they should

Figure 12-11.—Evolution of equivalent circuit of lighthouse tube oscillator.

tuning of the cathode line; the cathode tuning serves principally to control the amount of feedback. If feedback is too small, oscillations are weak and may cease completely; if feedback is too great, power consumption in the grid circuit becomes too large. This results in a decrease in output of the oscillator. The value of C (hence of the cathode tuning) has some effect on the frequency of oscillations, but since C and C_{pk} are in series, and C is usually much larger than C_{pk}, C must be changed considerably to appreciably affect the frequency.

TUNING

Since the tuning of the plate line determines the resonant frequency of the plate circuit, which in turn determines the amount of inductance represented by the plate circuit at the oscillator frequency, the plate tuning is the chief control of the oscillator frequency. It has a secondary effect of feedback since C is determined by the relative frequencies of the cathode circuit and of the oscillator. Thus the plate line is tuned to give the correct frequency and the cathode line to adjust feedback for maximum output from the oscillator; but, since there is some interaction, it will be necessary to readjust each line for maximum accuracy.

TRAVELING WAVE TUBE

The traveling wave tube (TWT) is not a new device. It was invented during the latter part of World War II, but due to the instability of the earlier models, it saw no practical use at that time, although its remarkable capabilities and some of its potential applications were well known. The Navy retained an interest in the device because of its potential applications in the fields of communications, radar, and electronic warfare (EW).

Development of the early radars was rapidly followed by the development of techniques to deceive and jam them. The evolution of radar has been partially the result of a continuing need to stay ahead of any new countermeasure tactics which might compromise the radar's effectiveness.

The trend in search radars has been toward higher power and toward electronic counter-countermeasures (ECCM) techniques that will increase visibility despite jamming. A good antijamming radar must be able to shift frequency quickly (and, if possible, over a wide bandwidth) to avoid the jammer's frequency. Similarly, the trend in EW has been toward wide bandwidth capability, where the jammer amplifies wideband noise or may deceptively retransmit the radar pulse to offset the radar's frequency shift tactics.

Since wide frequency bandwidths are essential to the employment of such tactics, an amplifying device capable of broad operating ranges with sufficient output power and efficiency was needed. The TWT appeared to offer promise in these areas; and the Navy has been responsible for many of the primary advancements in the development of equipment to fulfill this promise.

PRINCIPLES OF OPERATION

Figure 12-12 is a simplified sketch of one type TWT structure. At the left of the diagram is the electron gun assembly. The cathode, when heated, emits a continuous stream of electrons. These electrons are drawn through the anode, focused into a tight, narrow beam, forced to travel the length of the

1982

leave a small, round hole in the paper no larger than a fine line. Since the same center is often used for both the bow pen and the compass, it is best that needles on both be the same size. If the compass needle is noticeably larger, either use it without pushing it into the paper or grind it until it is the correct size. With some instrument sets, a special disk is provided for use when a hole in the paper at the center of a circle or ark is especially undesirable. This disk may be composed of plastic and metal or of bone, and it has three sharp points around its outside diameter which, when they are pushed into the paper, hold the disk in position.

Figure 3-51.—(A) Evening legs of dividers. (B) Sharpening divider needle points.

To make a compass needle smaller, wet one edge of the oilstone and place the needle with its shoulder against this edge. Then grind it against the oilstone, twirling it between your thumb and forefinger. (See fig. 3-52.) Test it for size by inserting it in a hole made by another needle of the correct size. When it is pushed as far as the shoulder, it should not enlarge the hole.

Figure 3-52.—Shaping a compass needle.

BOW INSTRUMENTS

Bow pens and pencils are used for drawing circles smaller than 1 inch in diameter. Bow dividers are used principally for transferring small measurements on a drawing. As you can see in figure 3-53, the bow instruments are merely small instruments which have a screw acting against a spring for adjusting the spread of the legs. These instruments are used in the same manner as the compasses and dividers previously described.

The screw threads on bow instruments are delicate, and care should be taken never to force them. When you increase the spread of the legs, hold them together lightly to release the tension on the setscrew and to decrease the wear on the threads. Take care to keep the threads free from rust or dirt.

Figure 3-53.—Bow instruments: (A) bow pen; (B) bow pencil; (C) bow dividers (D) drop bow pen.

The drop bow pen (fig. 3-53D) is not one of the standard instruments. However, for some jobs it it essential. It is used to draw small circles with diameters of less than a quarter of an inch, such as rivet holes on structural drawings. As the name indicates, the pen assembly is free to move up or down and to rotate around the main shaft. Holding the pen in the raised position, adjust the setscrew to give the desired radius. Then gently lower the pen to the paper surface and draw the circle by rotating the pen around the shaft. These instruments are generally used for drawing a large number of small identical circles. They are also available as a combination drop bow pen and pencil.

RULING PENS

It requires far more experience to do a professional job in ink than it does to do one in pencil. An apprentice draftsman starts with a pencil. After he has learned to draw with a pencil, using the T-square, triangles, curves, and compass, he can begin to use pens.

Figure 3-54.—Ruling pens: (A) spring type; (B) hinged-blade type.

Figure 3-55.—Special varieties of the ruling pen: (A) detail pen; (B) contour pen; (C) railroad pen.

The ruling pen is used for ruling lines of uniform width with the T-square, triangles, or other guides. It should not be used for freehand work. It consists of two steel blades, called nibs, attached to a handle. The blades are of equal length, narrowed at their tips. (See fig. 3-54.) A setscrew is used for adjusting the distance between the nibs at the tip to correspond to the width of line desired. Tightening the screw brings the nibs closer together so that the pen makes a thinner line.

The standard ruling pen has an adjustable spring blade, limber enough to permit opening it wide to clean the inside of the nibs. Another type has a hinged blade, which allows the pen to be opened, cleaned and snapped back in place with the nibs the same width apart. This is convenient if you have to do a long piece of work which requires many lines of the same width.

There are several useful variations of the standard ruling pen. (See fig. 3-55.) The detail or Swede pen is similar to the standard pen except that the blades are wider and have a greater ink capacity. It can be used for very heavy ink lines as well as for light lines. The contour pen has blades attached to a shaft which rotates in-

side the hollow handle, and it is particularly useful for drawing sharp, precise curves. The railroad pen has two sets of blades which can be set to draw parallel lines of equal width or of different widths.

The bow pen and the pen attachment for the compass are also variations of the standard ruling pen. They should be filled and cleaned like the ruling pen.

Filling the Pen

Before filling a ruling pen, be sure that it is clean. New pens should be washed to remove the thin film of oil that is usually on them when they come from the manufacturer. Adjust the screw to set the nibs to the approximate line width you want. The ordinary 2-ounce bottle of India ink is provided with a quill, which is

Figure 3-56.—Using ink-bottle quill to fill a ruling pen.

fastened to the stopper, for use in filling a ruling pen. Figure 3-56 shows how the quill from the ink bottle is used to fill the pen. Insert it between the nibs of the pen until the ink rises to about 3/16 of an inch from the tip. If you do not have a quill attached to the cork, an ordinary writing pen dipped in ink and passed between the blades of the ruling pen will fill it satisfactorily. Overloading will cause a blot or an uneven line.

Before you start to draw with the ruling pen, carefully remove any ink from the outside of the blades and test the width of the line on a scrap of your drawing paper. If the line is not the right width, make a final adjustment of the setscrew.

Drawing Lines

When drawing, hold the ruling pen with the setscrew pointed away from you. Be sure that both nibs touch the paper. The pen should be almost upright, with a slight tilt in the direction in which you are drawing. (See fig. 3-57.)

Figure 3-57.—Drawing lines with a ruling pen.

To draw clean, uniform lines, you must hold the pen properly. If the handle is tilted toward the guide, one of the nibs will lift from the paper and your line will be weak. If the nibs are pressed too hard against the guide, you will force one closer to the other and your line will not be uniform in width. If you tilt the handle of the pen away from the guide, the nibs will be thrown in contact with the guiding edge and ink may run under it. Some of the results of improper use of the pen are shown in figure 3-58.

Figure 3-58.—Defective ink lines and their causes.

When you use a ruling pen with a T-square or straightedge, make long lines with a whole-arm movement by sliding your pen hand along the blade, while you keep the straightedge steady with your other hand. Just before reaching the end of a line, slow down and finish with a finger movement to keep from overrunning the line. For greater control in stopping, draw short lines and the ends of long lines with a finger movement. When the end of a line is reached, lift the pen vertically, and carefully remove the guide.

Draw horizontal lines from left to right, starting at the top of the drawing and working down. (If you are lefthanded, you will, of course, draw these lines from right to left, and similarly reverse many of the directions given in this book.)

Vertical lines are usually drawn in an upward direction and from left to right. However, when you have to draw a number of vertical lines or lines slanted in the same direction, how you draw them will be governed by the source of your light and the way you have found that you can draw vertical lines with greatest control.

Let the first lines dry before starting to draw any intersecting lines. Watch carefully when you draw one line across another line. If the ink starts to run down the dry line under your straightedge, lift the pen quickly from the drawing and move the straightedge carefully.

If the ink is stubborn and refuses to flow, draw the pen tip quickly over a piece of scratch paper. If it is still sluggish, examine your pen to see if it needs cleaning or if it is worn.

Figure 3-59.—Shapes of ruling pen nibs. (A) worn; (B) correct; (C) too pointed; (D) too rounded; (E) too curved.

Caring for the Pen

Clean your pen by dipping the tip in water or in water with a little ammonia in it or in a pen-cleaning solution. Then wipe the blades thoroughly, inside and out, with a soft, lintless cloth.

You will have to wipe your pen several times during the course of a few hours of work, because ink hardens in the pen very rapidly. Don't subject your pen to unnecessary wear by stroking it too often on scratch paper when the ink fails to flow easily; clean it instead. Always put it away clean, with its blades well separated to release the tension on the steel.

Sharpening the Ruling Pen

High quality is especially desirable in a ruling pen. If the nibs are of low quality steel, it will be more difficult to keep them sharp. A good pen will usually be sharp when it comes from the manufacturer, but a cheap pen may need sharpening before it is used.

When you start having difficulty drawing fine lines or getting the ink to flow from your pen, check it for signs of wear. Hold the nibs toward you in a good light, and if they are worn, you will see a bright spot on the tip of each nib which is not present on a sharp pen. This spot indicates a flat surface that has been formed by wear. (See fig. 3-59A.)

A ruling pen that has become dull may be sharpened on a fine oilstone if extreme care is

Figure 3-60.—Shaping a ruling pen.

used. To restore the nibs to their original parabolic shape, hold the pen in a vertical plane and bring the blades into light contact with the stone. Then whet the pen back and forth through an angle of about 120 degrees. (See fig. 3-60.) To sharpen each nib of the pen, hold the outside surface nearly flat on the surface of the oilstone and whet with a rotary motion to conform to the shape of the nib. (See fig. 3-61.)

Figure 3-61.—Sharpening a ruling pen.

Take care not to alter the parabolic shape of the ends. The edges should not be too sharp or they will cut the paper when the pen is used. Any burr should be removed from the inside of the blades with a piece of leather or emery paper. The inside surface should never be stoned, since stoning may give it a slight convexity, which is very undersirable.

There is another method of sharpening ruling pens which requires less skill. Place a fine grain emery paper on a base of sponge rubber or a towel folded several times. Shape the ruling pen on the emery surface just as you would shape it on an oilstone. Then open the nibs and place the back of each one in turn at an acute angle in full contact with the surface of the emery paper. (See fig. 3-62.) Draw the pen repeatedly over the surface of the emery paper, always in a direction toward the handle of the pen and with sufficient downward pressure so that the paper becomes depressed into a channel fitting the contour of the nibs. Hold the pen firmly and prevent it from turning, so that the edges of the nibs are in equal contact with the paper. When the nibs are sharp enough, grind the inside surface lightly with the emery paper to remove any burrs that may have formed.

Figure 3-62.—Sharpening the nibs of a ruling pen on emery paper.

CARE OF CASED INSTRUMENTS

Your instruments may be issued to you one by one or as a set in a case. If possible, it is best to keep them in a case, since the case protects them from falls or unnecessary pressures. Then, too, the lining of the case is usually treated with a chemical which helps prevent the instruments from tarnishing or corroding.

To protect instruments from rusting when they are not in use, clean them frequently with a soft cloth and apply a light film of oil to their surface with a rag. Joints on compasses and dividers should not be oiled. A knife edge or an abrasive should never be used to clean instruments, since, when the surface finish is worn or scarred, they are more subject to corrosion.

It is sometimes difficult to judge the quality of drafting instruments by appearance alone. Often their characteristics become evident only after they are used. Usually, cheap quality instruments have a mass-production appearance, with little machine finishing and with designs that permit rapid assembly. On the other hand, high quality instruments are usually correctly sharpened, adjusted, and packaged in a good quality case when they come from the manufacturer. Some instruments, although accurately made and capable of fine adjustment, are lacking in rigidity. For this reason, the simple, sturdy instruments are often most practical. Before you select instruments, look for the brand name and try to learn something about the reputation it has with experienced draftsmen.

As a Navy draftsman, you are not expected to buy your own instruments. These are furnished by the Navy. If you have professional pride, you will care for them as you would your own. However, when an instrument is defective or worn beyond repair, do not hesitate to ask that it be replaced. Remember that the quality of your work is of first importance.

PENCILS

The selection of a grade of pencil lead is to some extent a matter of a particular draftsman's personal preference. The 18 grades of pencil lead from 9H (hardest) to 7B (softest), may be broadly divided into three general categories as follows:

9H to 4H . . . . . hard
3H, 2H, F, HB . . . . . medium
B to 7B. . . . . soft

In general, the soft lead is used more for illustrative than for technical drafting. The medium lead is used for general-purpose work, for tracing, and for lettering. The softer hard lead is used for line work in machine drawing, the harder hard lead for graphs, charts, or diagrams requiring a high degree of accuracy in the drawing.

The standard leads described above are used primarily on paper and linen, although they may be used on film. However, there are now leads on the market designed specifically for use on drafting film. The grade designations vary with the manufacturer; three of these are K1 through K5, 2S through 6S, and E1 through E5.

If you want to keep your drawing clean, do not use leads that are so soft that they smear easily. Use a very sharp point when you point off directions with the scale. Try to select a pencil which will make a good line on the particular surface you are using. With such a pencil, it should not be necessary to put so much pressure on it that it makes a dent in the paper. On most fine tracing paper, H to 3H pencils are best.

In drawing with a pencil, the width of the line you make depends on the sharpness of your lead, not on the pressure you put on it. If the tip of the lead is very sharp, you can draw a thin, black line or a thin, gray line, depending on the pressure of your pencil on the paper. If the tip is slightly duller, you can draw a medium black line or a medium gray line. Wide lines are drawn with pencils with blunt tips.

Drafting room pencil sharpeners cut the wood away from the lead without cutting the lead and leave about 3/8" of the lead exposed as shown in figure 3-63. If no such sharpener is available, use a knife or a razor blade to cut the wood away from the pencil lead. A pencil should always be sharpened at the unlettered, never at the lettered, end. The reason is, of course, to preserve the symbol which indicates the grade of the pencil.

Figure 3-63.

Many draftsmen prefer lead holders, which are mechanical clutch-type pencils in which you may insert any grade of lead.

Figure 3-64.—a. Conical point.
b. Chisel point. c. Elliptical point.

The lead exposed in either a wooden pencil or a lead holder must be dressed, or pointed, before it can be used. The conical point shown in figure 3-64 is most commonly used. However, many draftsmen claim that if you draw a long line with the narrow part of the chisel point the lead does not wear down as rapidly and the line is more even. (See fig. 3-64B.) Others maintain that pencil leads, as manufactured, are harder on the outside and that the elliptical point takes advantage of the hardest part of the lead. These draftsmen use the elliptical point, which is normally used in the bow pencil, in doing other drawings.

If you use a lead with either a chisel or an elliptical point, you must keep the pencil from shifting in your hand as you draw. If the pencil shifts so that the wide part of the point slants across the line, the line will vary in width. Since this is not easy to prevent, it is better for the beginner to work with a conical tip.

When you are making mechanical drawings in pencil, hold the pencil in an almost vertical position, just as you would hold a pen. Press the lead against the guiding edge only enough to hold the lead in contact with it. When you are using a lead with a conical tip and must draw a long line with it, revolve the pencil slightly as you draw and the lead will wear evenly, producing a more even line.

Keep a pad of sandpaper by your drawing table. These come with the sheets of sandpaper

lightly glued together at the edges and attached to a small wooden paddle. (See fig. 3-65.) Some draftsman tack their sandpaper pad to some steady surface within reach, so that they need not use their hands to steady it. This eliminates the chance of their getting loose graphite dust on their fingers. If you want a clean drawing, keep your hands clean.

Figure 3-65.—Flat sandpaper pad with wooden handle.

To sharpen a lead to a conical point, rotate the pencil as you rub the tip on the pad. This keeps the abrasive action of the pad even on all sides of the lead. (See fig. 3-66.)

There are presently on the market various mechanical pencil pointers which create a conical point. These are rotating devices, some of which clamp to the table, which contain either metal file blades or sandpaper to cut the lead.

To sharpen a lead to a chisel point, hold the pencil on one side as you rub it on the pad until the lead is worn halfway through at the tip. Then turn it over and sharpen it the same amount on the other side. Many draftsmen who use the chisel point make a couple of final rubbings on the sandpaper pad to cut off the corners of the chisel and to narrow it so that it is easier to handle.

Figure 3-66.—Sharpening a lead to a conical point on the sandpaper pad.

When you want to sharpen a lead to an elliptical point, the exposed lead must be at least 3/8 of an inch long. Rub the lead on the sandpaper pad on one side only, holding the pencil at an oblique angle to the pad.

Before you start to draw with a newly sharpened lead, test it on a small piece of scratch paper. Use a piece exactly like the paper on which you are drawing.

ERASERS

Figure 3-67 shows just a few of the many types of erasers available. The first is a rubberless vinyl eraser for use on films and cloth. The next is a plastic eraser for use on film, cloth, and paper. The third is typical of the more ordinary pencil and ink erasers for use on linen and paper; these vary in softness—the softest are usually pink, the intermediate erasers are usually red, and the hardest are usually white. The last two are gum cleaning erasers. To clean finger marks or smudges from the surface

Figure 3-67.—Erasers.

of the drawing paper, use the artgum eraser. When you erase pencil lines, be careful not to use to hard an eraser, since such an eraser will damage the surface of the paper. To remove eraser crumbs from the drawing after each erasure, use a dusting brush such as the one shown in figure 3-68.

Many draftsmen also use kneaded erasers. These are made from snythetic rubber or plastic and may be kneaded in the bands to form a fine point. They have the advantage of leaving

Figure 3-68.—Dusting brush.

few crumbs on the drawing and can be used to pick up graphite dust, rather than to rub it off.

An electric erasing machine such as the one shown in figure 3-69 is a timesaver when there is much erasing to be done, but it is hard to use on paper without damaging the surface. It has a hard eraser at its tip, which revolves very rapidly when the machine is turned on. To use it, touch it gently to the line to be erased. Any undue pressure on the eraser will cause it to bite into the surface.

Figure 3-69.—Erasing machine.

An erasing shield (see fig. 3-70) is a small plate of thin spring steel with holes of various shapes having been punched out. The open holes in the shield make it possible to remove unwanted lines while leaving other work untouched. Further, the sharp edge of the metal cuts away the smudged exterior of the eraser, permitting a clean portion of the eraser to rub against the surface of the drafting media.

In addition to artgum erasers, cleaning compounds include pulverized gum eraser particles which may be squeezed onto the drawing from a plastic squeeze bottle. Gum eraser granules are also packaged in cloth bags made of a soft mesh. The granules sift through the bag as it is rubbed over a drawing. The eraser pad is also

Figure 3-70.—Erasing shield.

excellent for precleaning to prevent later soil buildup.

Frequently, ink may be removed more easily from drafting media, especially linen, by scraping rather than rubbing. This procedure is facilitated by careful use of a steel eraser such as the one shown in figure 3-71.

Figure 3-71.—Steel eraser.

DRAFTING MEDIA

The quality of drafting media is very important. As with any other artist, draftsmen using good materials may not always produce top-notch work, but draftsmen using poor materials will never produce good work. For practice you may use inferior paper, since the drawing does not have to be duplicated, but never try to do a finished piece of work on paper with a grain in it. The grain will show up on contact prints of the drawing, and drawings are generally duplicated by contact printing methods. Drafting media in general use are described in the following paragraphs.

Detail paper is a heavy weight, opaque paper which is usually either buff or neutral green in color. It takes pencil well, but pencil lines on it are difficult to erase because a hard, sharp pencil makes impressions in the paper's heavy texture. When drawings are made on detail paper, they must be traced before blueprints or other duplicates may be made by contact printing methods, since detail paper is to opaque to be

used for this purpose. Due to changes in drafting practices, the need for drawing papers today is limited to the two extremes in the quality scale: the very highest grade, permanent drawing papers with the best possible erasing quality for maps or master drawings which are later photographed, and at the other extreme inexpensive school type of papers.
